**INFLUENCE OF TEMPERATURE
UPON THE
STRENGTH OF CONCRETE**

BY

J. ALBERT ANDERSON

AND

WALTER JOHN BUBLITZ

THESIS

FOR THE

DEGREE OF BACHELOR OF SCIENCE

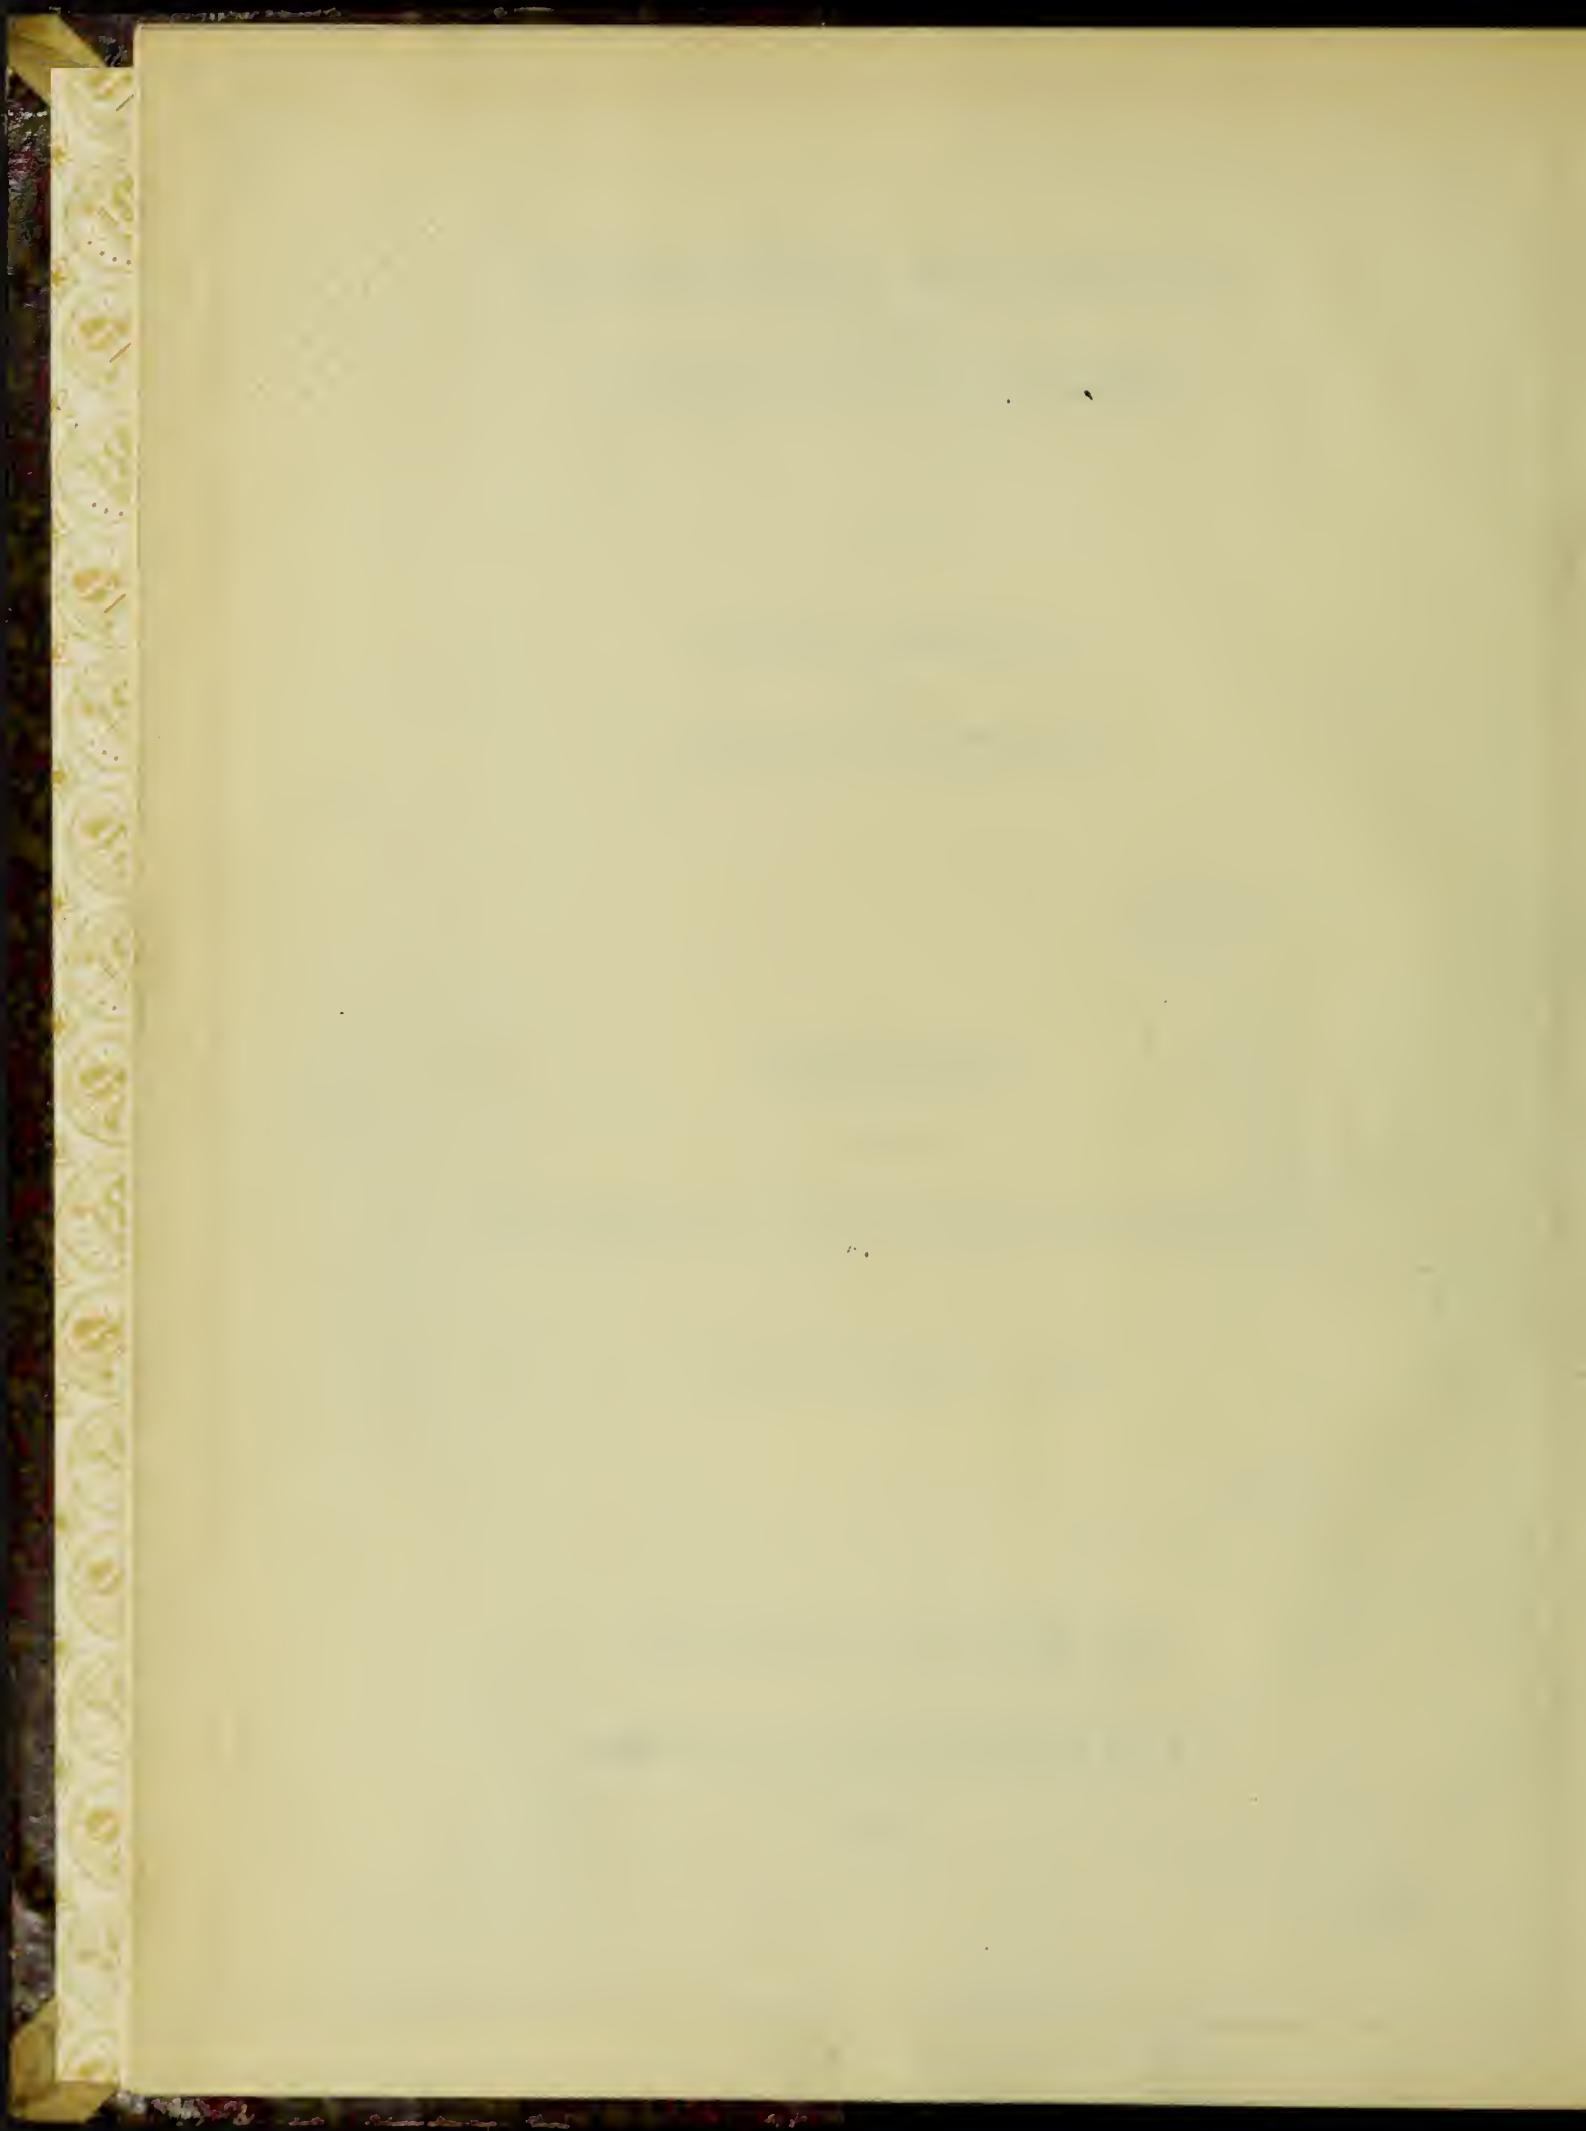

IN

CIVIL ENGINEERING

COLLEGE OF ENGINEERING

UNIVERSITY OF ILLINOIS

1914

1914
Anaa

UNIVERSITY OF ILLINOIS
COLLEGE OF ENGINEERING

May 25, 1914.

I hereby recommend that the thesis prepared under my direction by J. ALBERT ANDERSON and WALTER JOHN BUBLITZ entitled INFLUENCE OF TEMPERATURE UPON THE STRENGTH OF CONCRETE be accepted as fulfilling this part of the requirements for the degree of Bachelor of Science in Civil Engineering.

A. B. McDaniel
Assistant Professor of Civil
Engineering.

Recommendation concurred in:

Dr. O. Baker

Head of the Department of
Civil Engineering.

INFLUENCE OF TEMPERATURE ON THE STRENGTH OF CONCRETE.

I. INTRODUCTION.

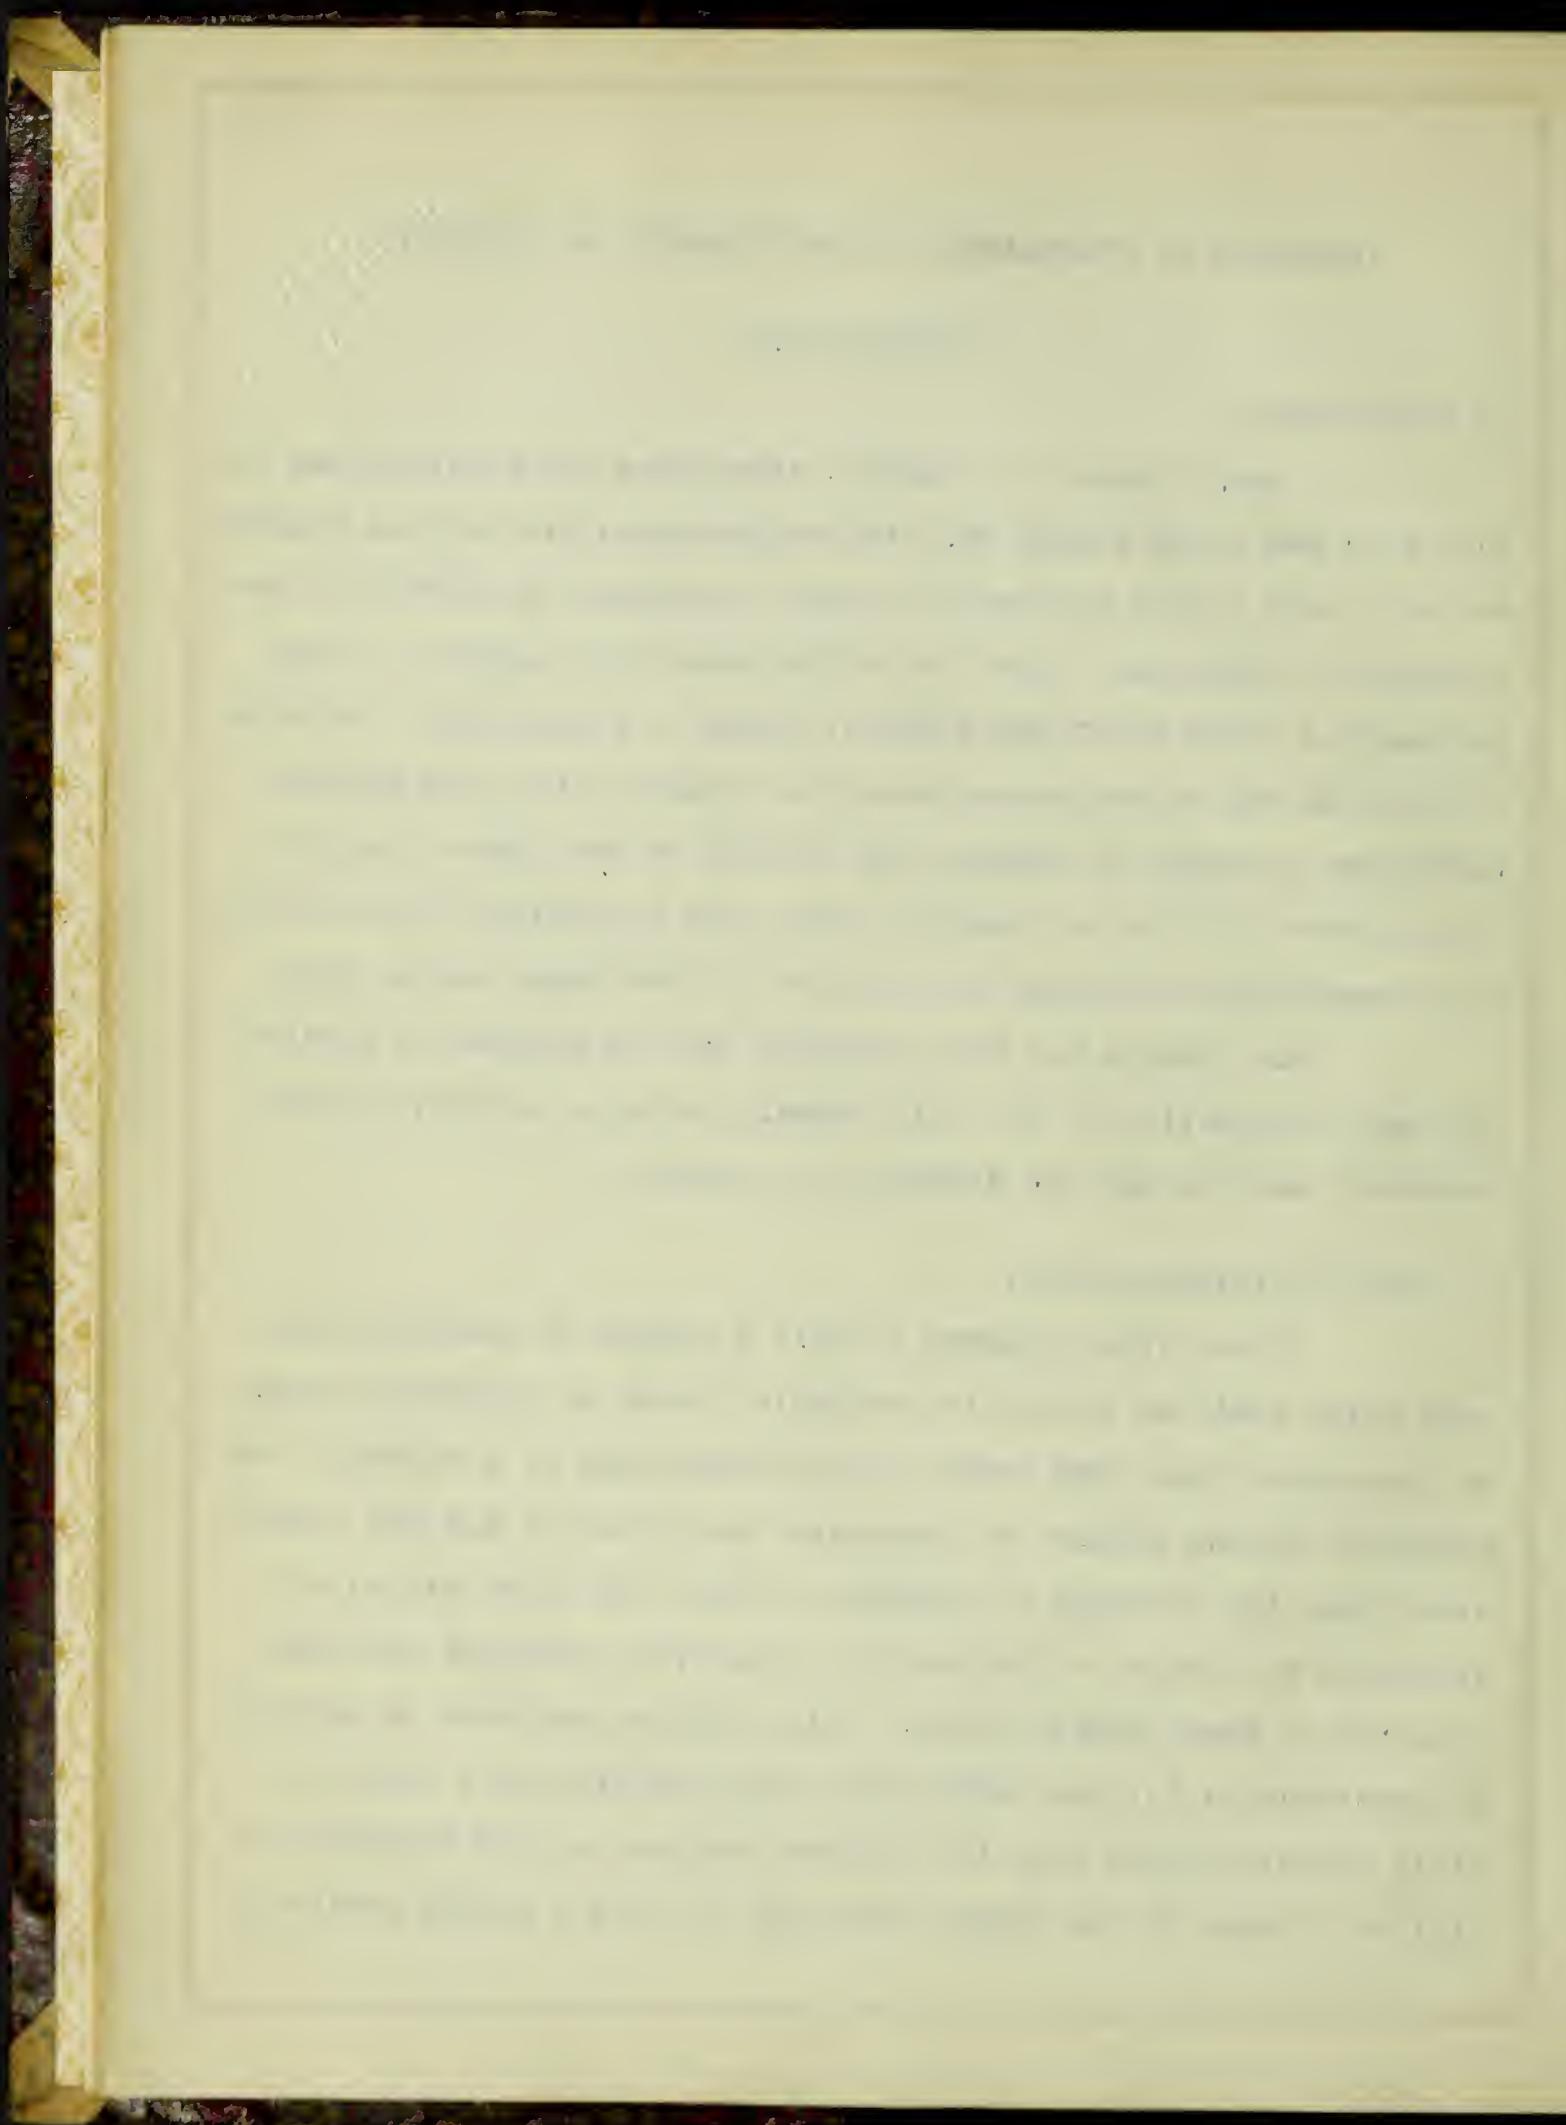

1. PRELIMINARY.

A large number of concrete structures are built during the late fall and early spring when the temperatures are low and usually varied. Very little information exists regarding the effect of variations of temperature upon the setting action of concrete. Such information would be of the greatest value to contractors, for with it the time can be determined when the concrete will have gained sufficient strength to warrant the removal of the forms. Many of the concrete failures of the past have been attributed to the existing temperature conditions and the lack of knowledge due to them.

This thesis has been prepared for the purpose of furnishing some information of the relationship existing between the temperature, and the age and strength of concrete.

2. SCOPE OF INVESTIGATION.

It was first planned to mold a series of concrete specimens which could be stored in available places at different ranges of temperature and then tested at different ages in a standard compression testing machine to determine the effect of age and temperature upon the strength of concrete. After the first series of specimens were made, a failure of a reinforced concrete building occurred at Cedar Rapids, Iowa. This building had been in process of construction for six weeks and it was believed as a result of field investigations that its failure was due to cold weather conditions. Hence it was deemed desirable to test a second series of

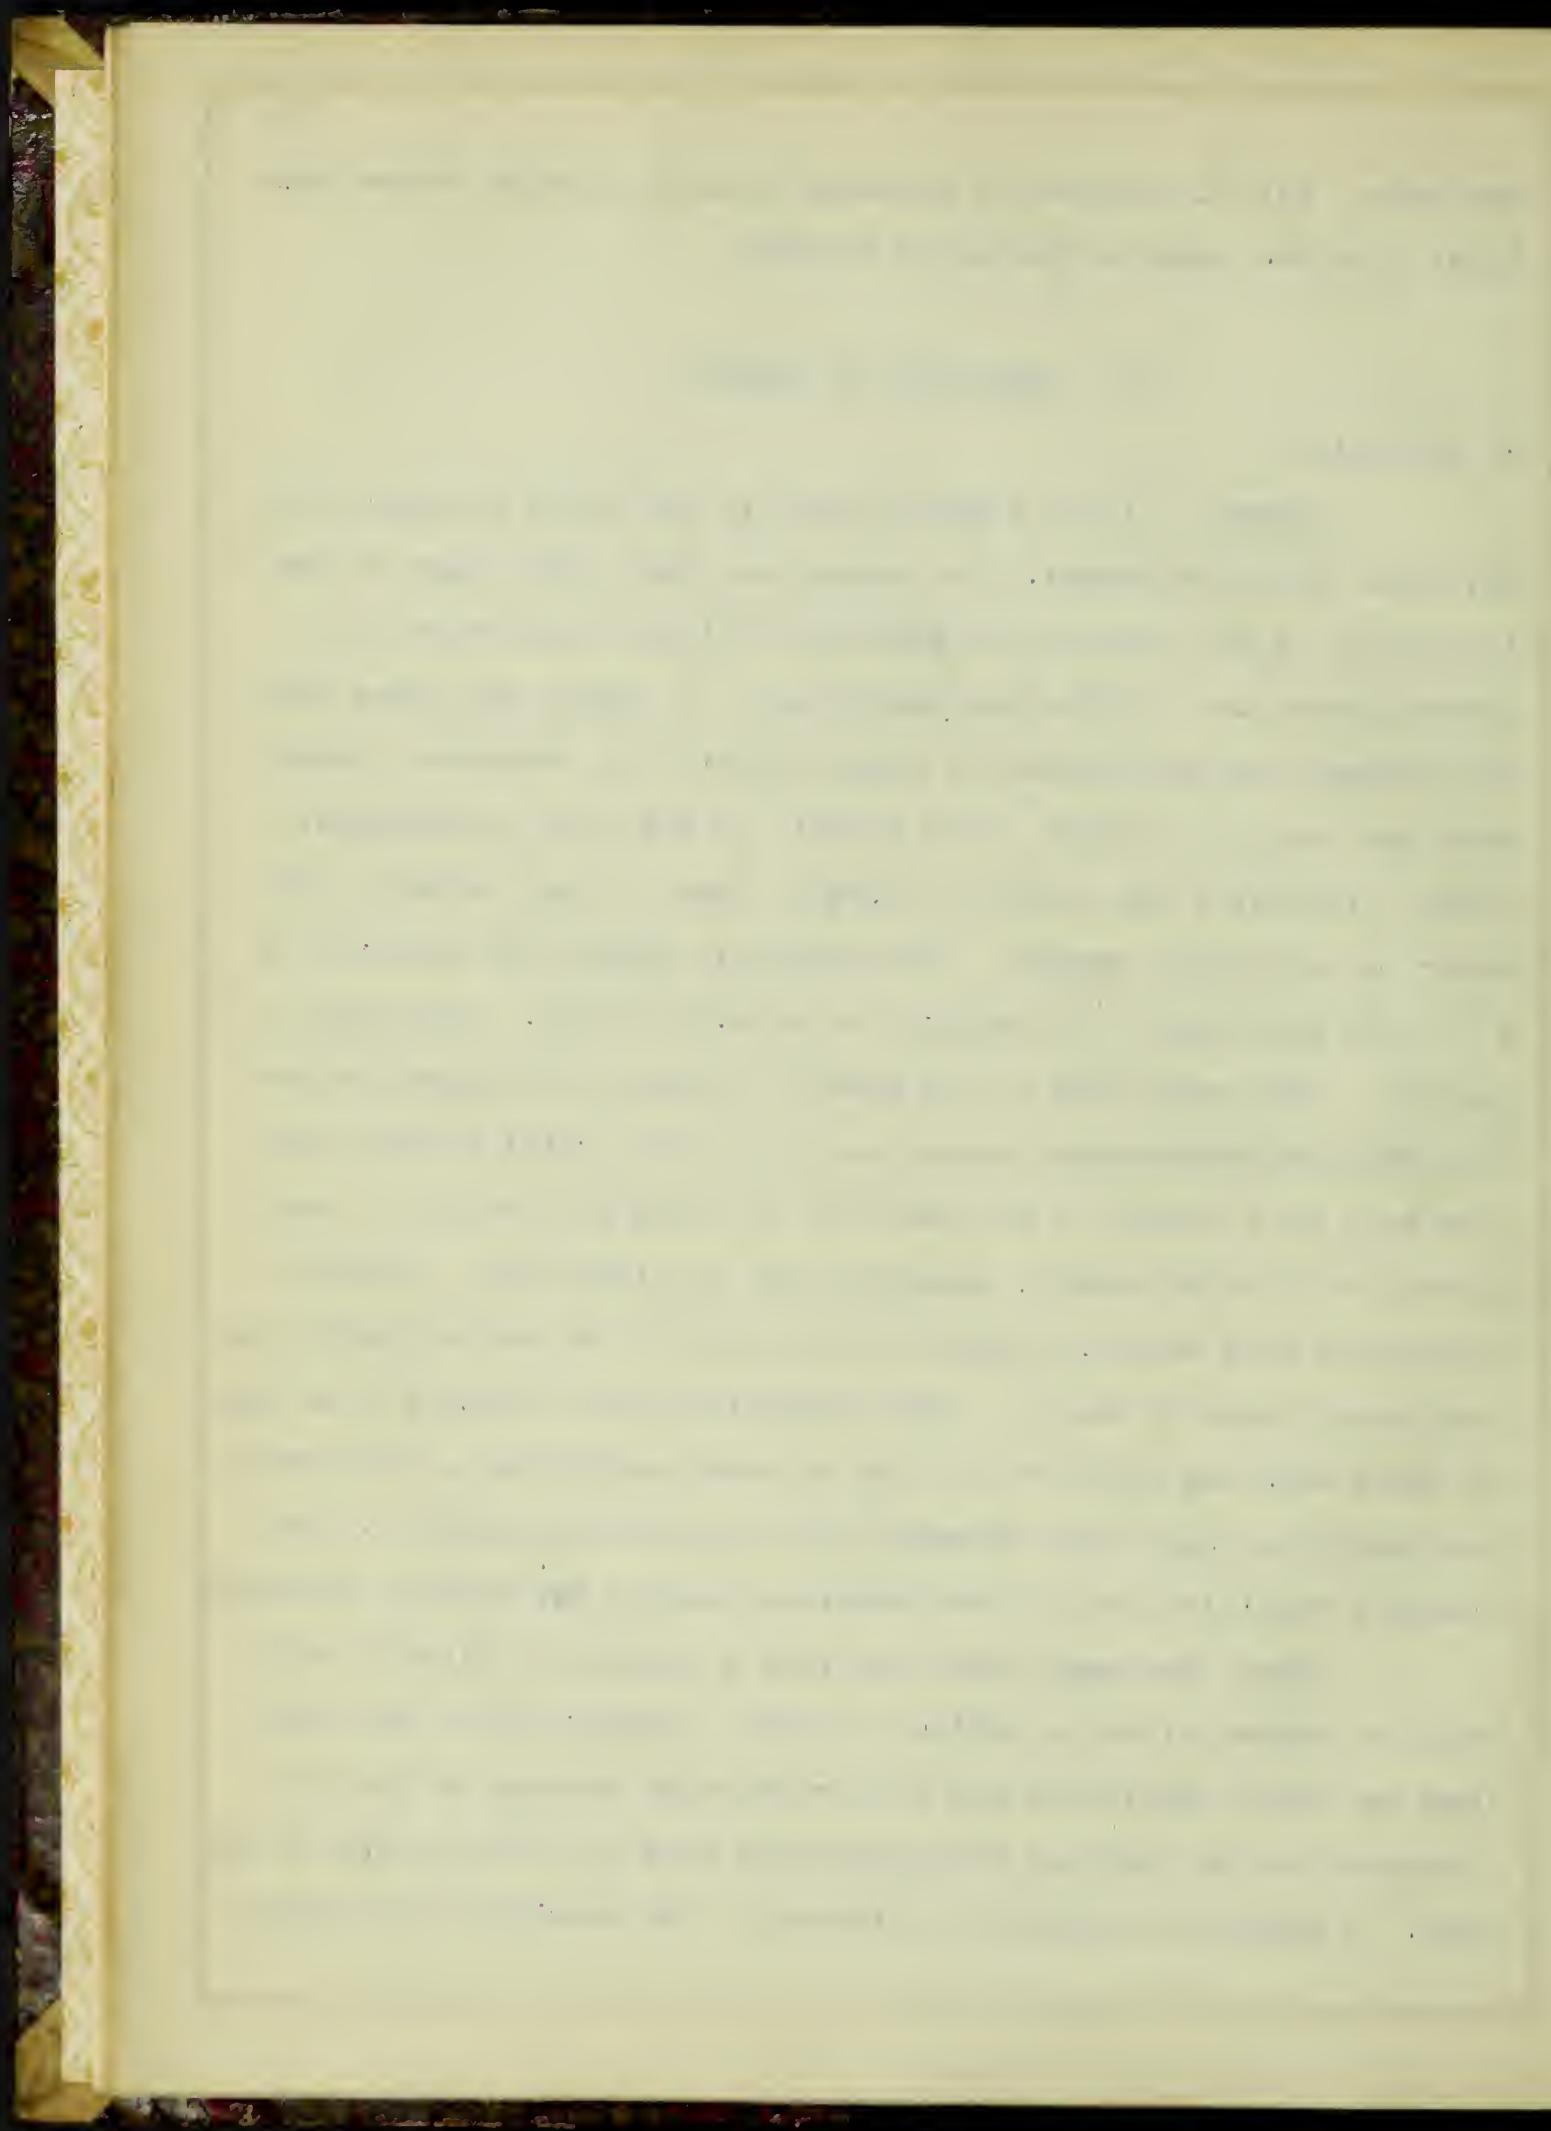

specimens, for the purpose of securing data which might throw some light upon the cause of the above failure.

II. PROCEDURE IN TESTING.

3. MATERIALS.

Cement. All the concrete used in the tests was made with Universal portland cement. The cement was taken from bags in the laboratory of the Engineering Experiment Station and stored in a covered metal can in the Road Laboratory. A sample was taken from the storage can and tested for normal plasticity, fineness, soundness and tensile strength. The results of the test to determine normal plasticity are given in Table 13, page 29, and indicate 23% water as the proper amount. Sieve analysis showed 16% retained on a No. 200 sieve and 2.9% retained on a No.100 sieve. See Table 14, page 29. Pats were made at the time of molding the briquettes and were examined after being stored one day in the moist closet; and then half were stored in air and half in water for 28 days. They showed no signs of cracks, discoloration or distortion. Sixteen briquettes were made and stored for one day in the moist closet, and then were placed in water. Eight briquettes were broken at the age of seven days and eight at the age of twenty-eight days. The average result for each test exceeded the minimum requirements of the Standard Specifications of the American Soceity for Testing Materials.

Sand. The sand used came from a deposit of glacial drift near the Wabash river at Attica, Indiana. Nearly all of the clay, loam and other impurities had been removed by washing at the pit. A covered box in the Road Laboratory was used for the storage of the sand. A sample was tested for fineness. The results of this test

are given in Table 15, page 30 ; and are shown graphically in Fig. 1, page 18.

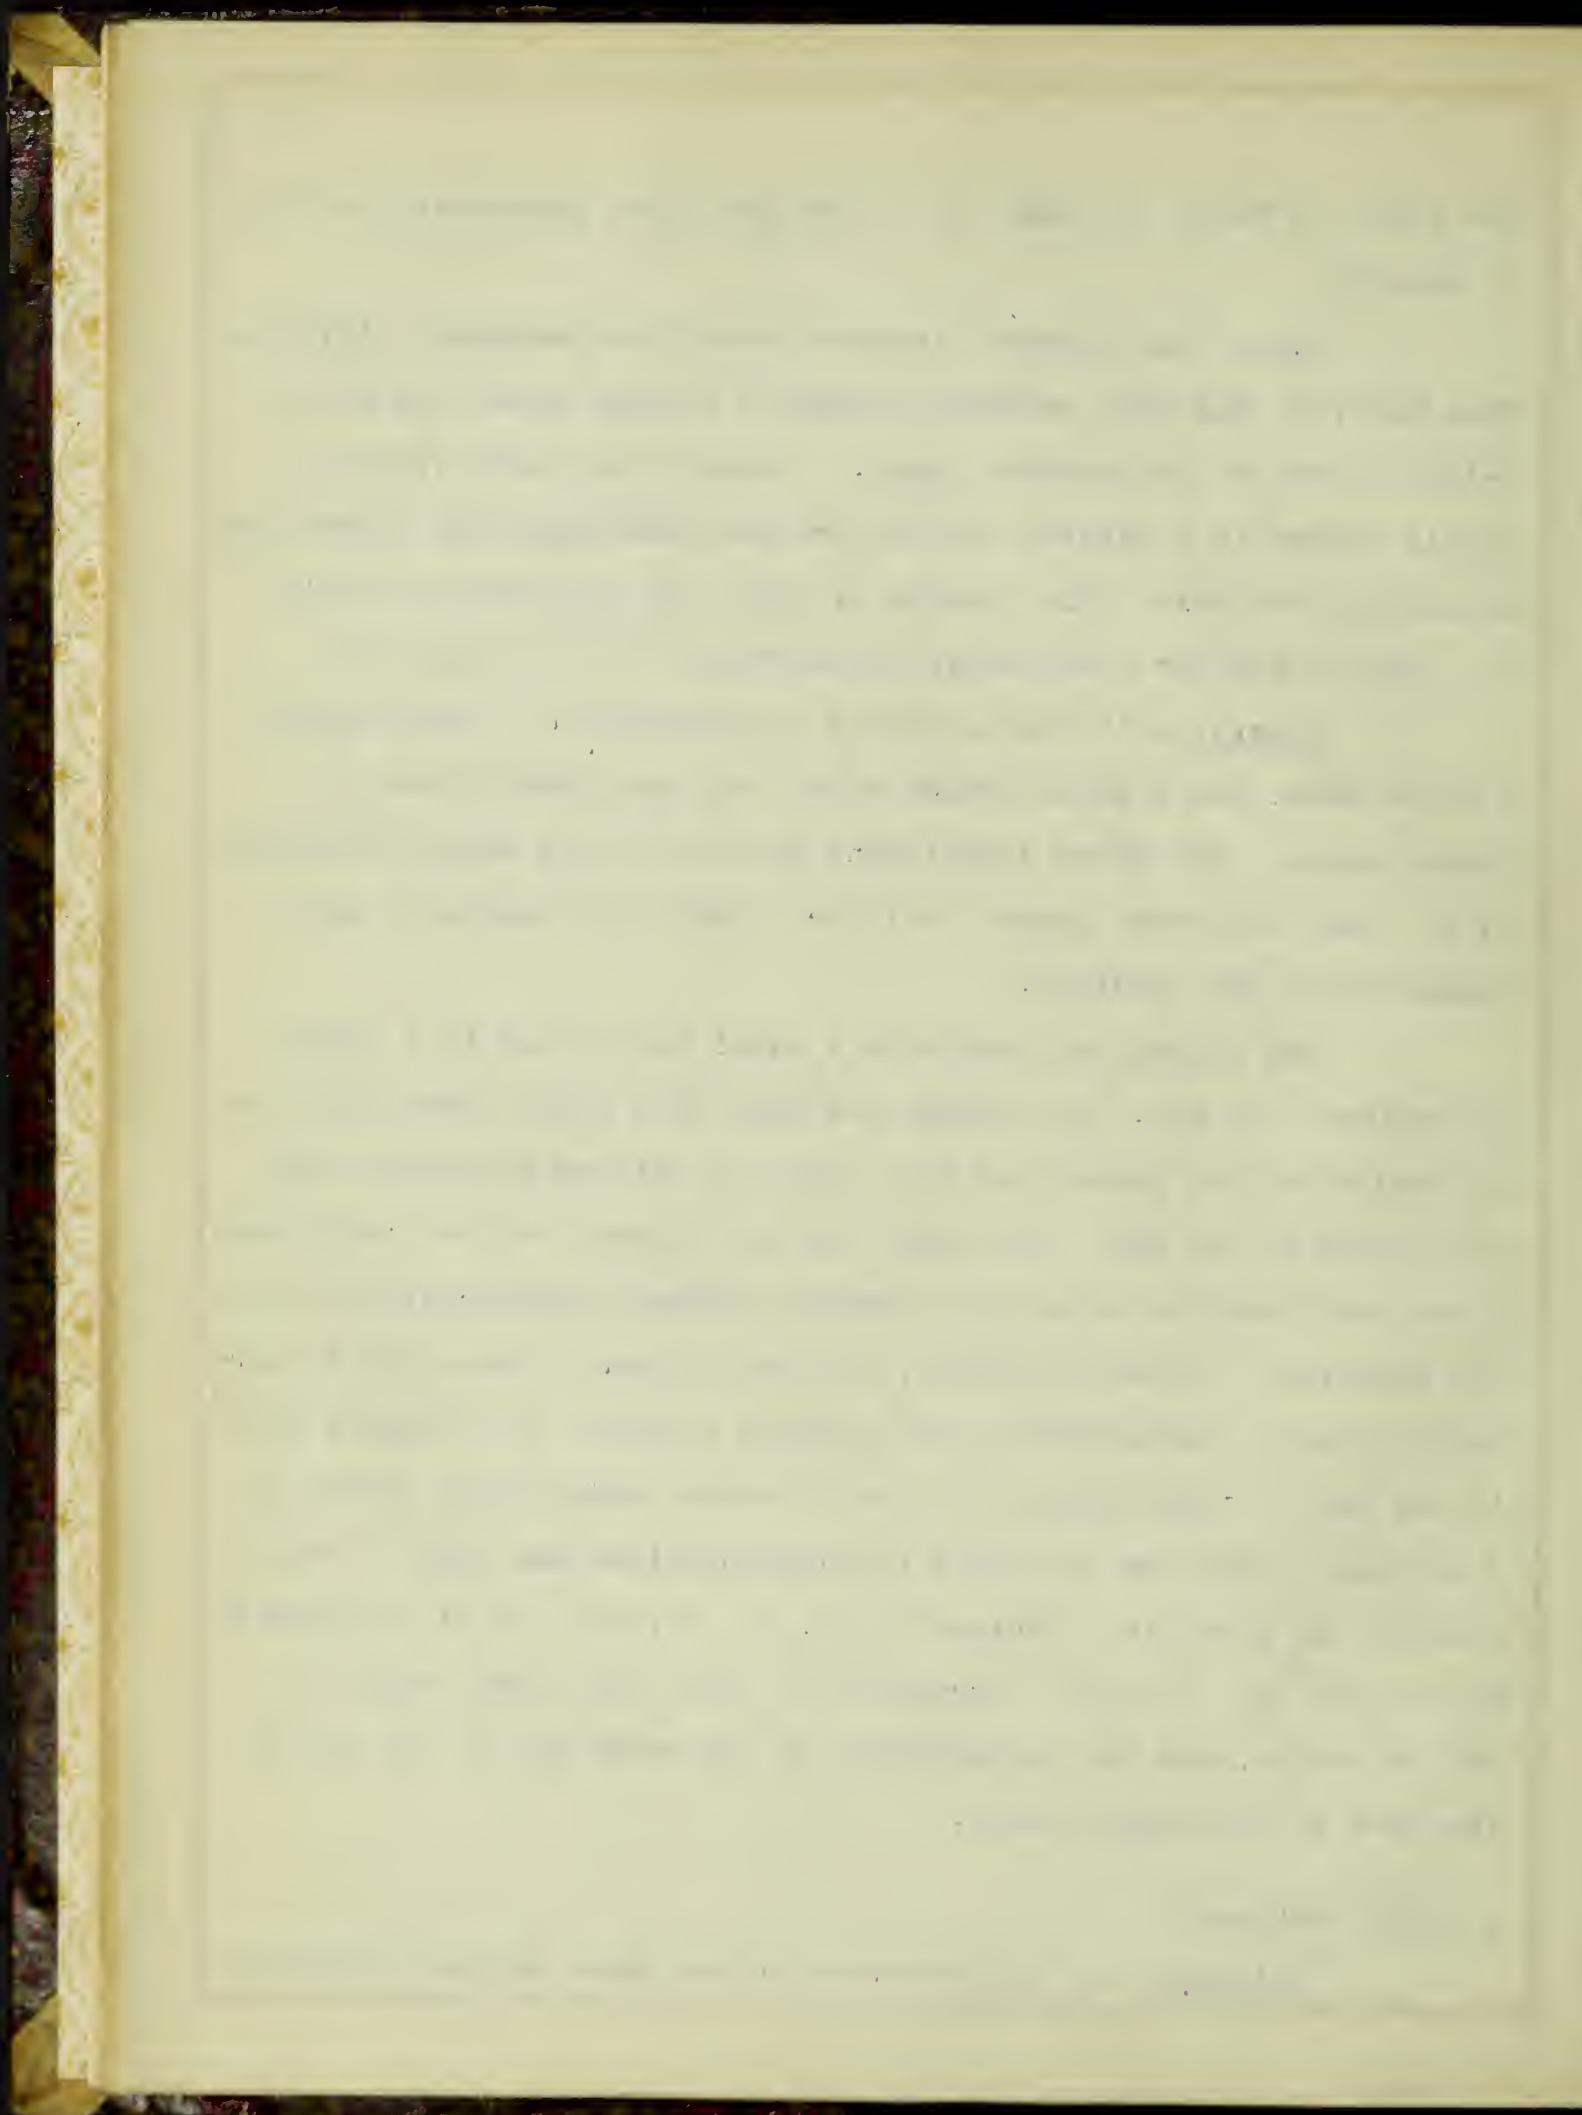

Stone. The crushed limestone came from Kankakee, Illinois. This material had been screened through a 1-inch screen and over a $\frac{1}{4}$ -inch screen at the crusher plant. A sample was taken from the supply stored in a covered box in the Road Laboratory and tested for mechanical analysis. The results of this test are given in Table 16, page 31 and are graphically represented in Fig. 2, page 19.

Concrete. All the concrete was composed of 1 part cement, 2 parts sand, and 4 parts broken stone; and was proportioned by loose volume. The three constituent materials were weighed separately so that the total amount would be slightly in excess of that required for one specimen.

The mixing was done with a steel trowel and in a large galvanized iron pan. The cement and sand were first mixed dry to a uniform color and spread out in a layer of uniform thickness over the bottom of the pan. The stone was then added, and the whole mass given four complete turnings to secure thorough incorporation of the dry materials. Water was added, and the material turned until thoroughly mixed. The concrete was gathered together in a compact mass in one end of the mixing pan so as to reduce evaporation losses to a minimum. The time of mixing for each specimen was kept as nearly constant as possible. Tables 18, 20, 22, 28, 29, and 31 on pages 33, 34, 35, 40, 41, and 43 respectively, give the total weight of dry materials, and the temperatures of the water and of the air in the room at the mixing table.

4. TEST SPECIMENS.

Molding. All the specimens of the first series, hereafter

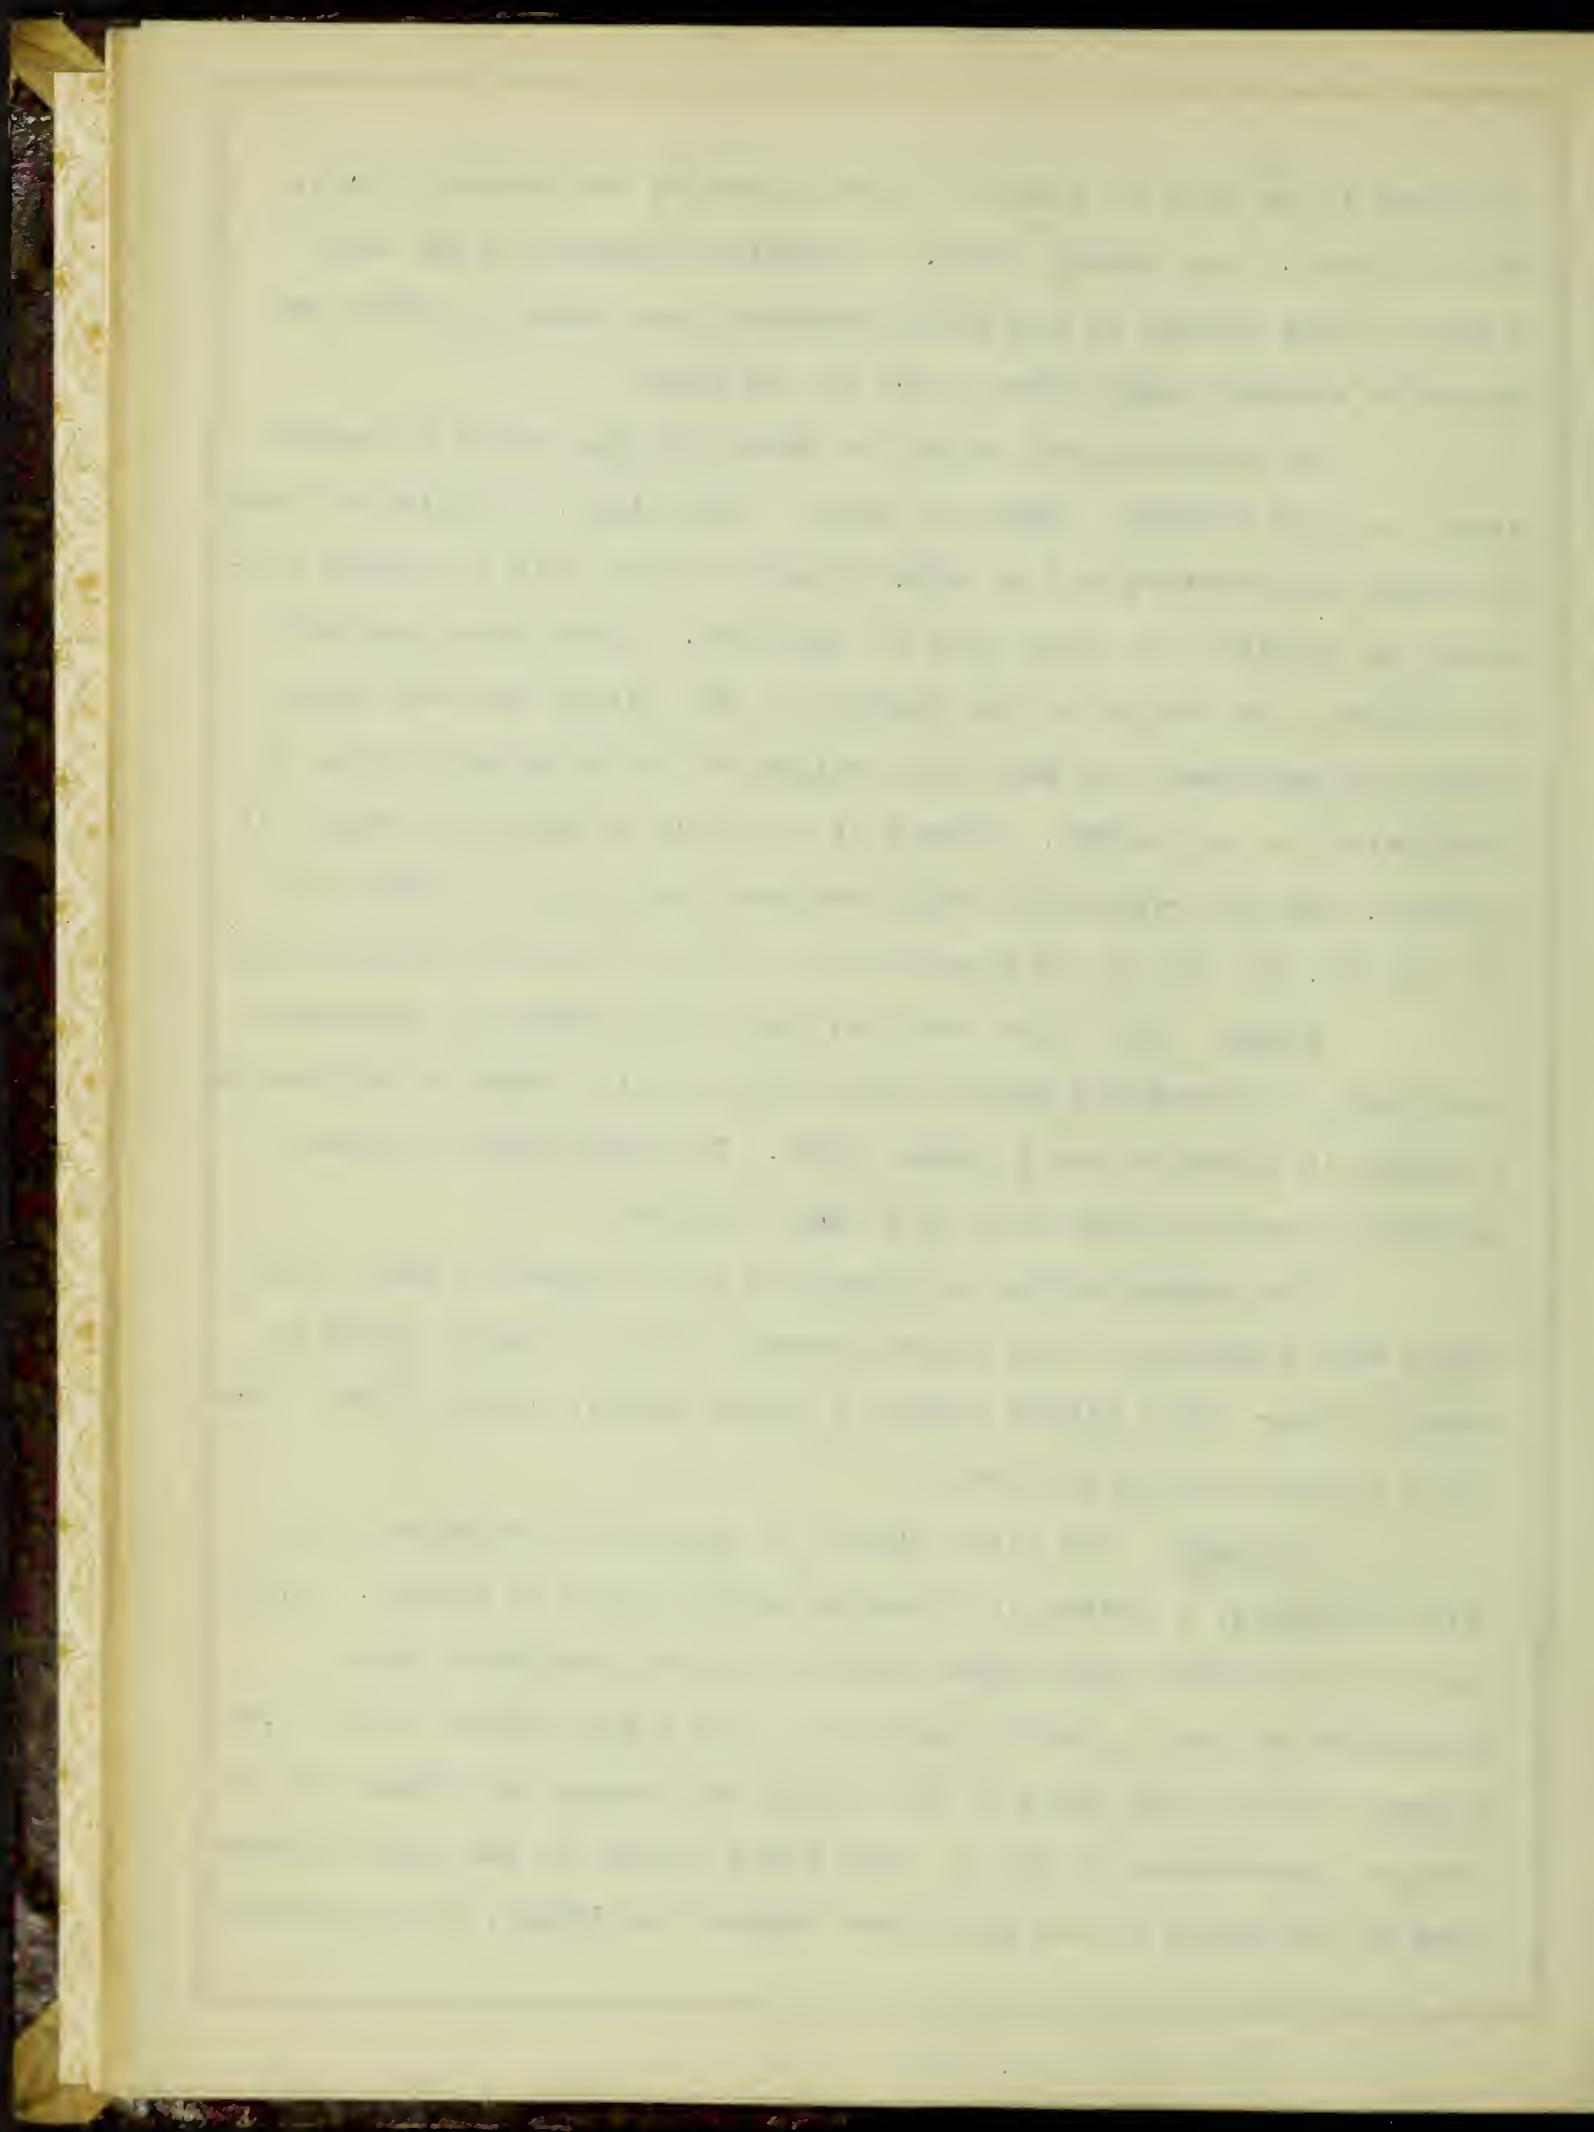

referred to as Sets A, B and C, were molded in the storage rooms, while those of the second series, hereafter referred to as Sets D, E and F, were molded in the Road Laboratory and moved to their respective storage rooms after a set of six hours.

The concrete was tamped by hand into the molds in layers about one and one-half inches in depth. The time of molding of each specimen was recorded and an effort made to keep this as nearly constant as possible for each type of specimen. After each specimen was molded, the weight of the residue in the mixing pan was determined and deducted from the total weight of the materials used, to ascertain the net weight. Values of the time of molding, weight of residue, and net weight for each specimen are given in Tables 18, 20, 22, 28, 29, and 31 on pages 33, 34, 35, 40, 41 and 43 respectively.

Forms. The forms used for the first series of specimens were made of galvanized sheet-steel bent into the shape of cylinders 6 inches in diameter and 6 inches high. Two adjustable, circum-scribing circular bands held each form together.

The second series of specimens were molded in cube forms which were composed of two 6-inch channels, held 6 inches apart by means of four steel plates spaced 6 inches apart, making three forms for a 6-inch cube in each mold.

Storage. The first series of specimens comprised forty-five cylinders, 6 inches in diameter and 6 inches in height. This series was divided into three sets of fifteen specimens each, designated as Set A, Set B, and Set C. Set A was stored in the ice-storage room of the plant of the Smith Ice Company in Urbana, at an average temperature of 30° F. Set B was stored in the meat storage room of the plant of the Smith Ice Company in Urbana, at an average

temperature of 48.5° F. Set C was stored in the Cement Laboratory at an average temperature of 72.8° F.

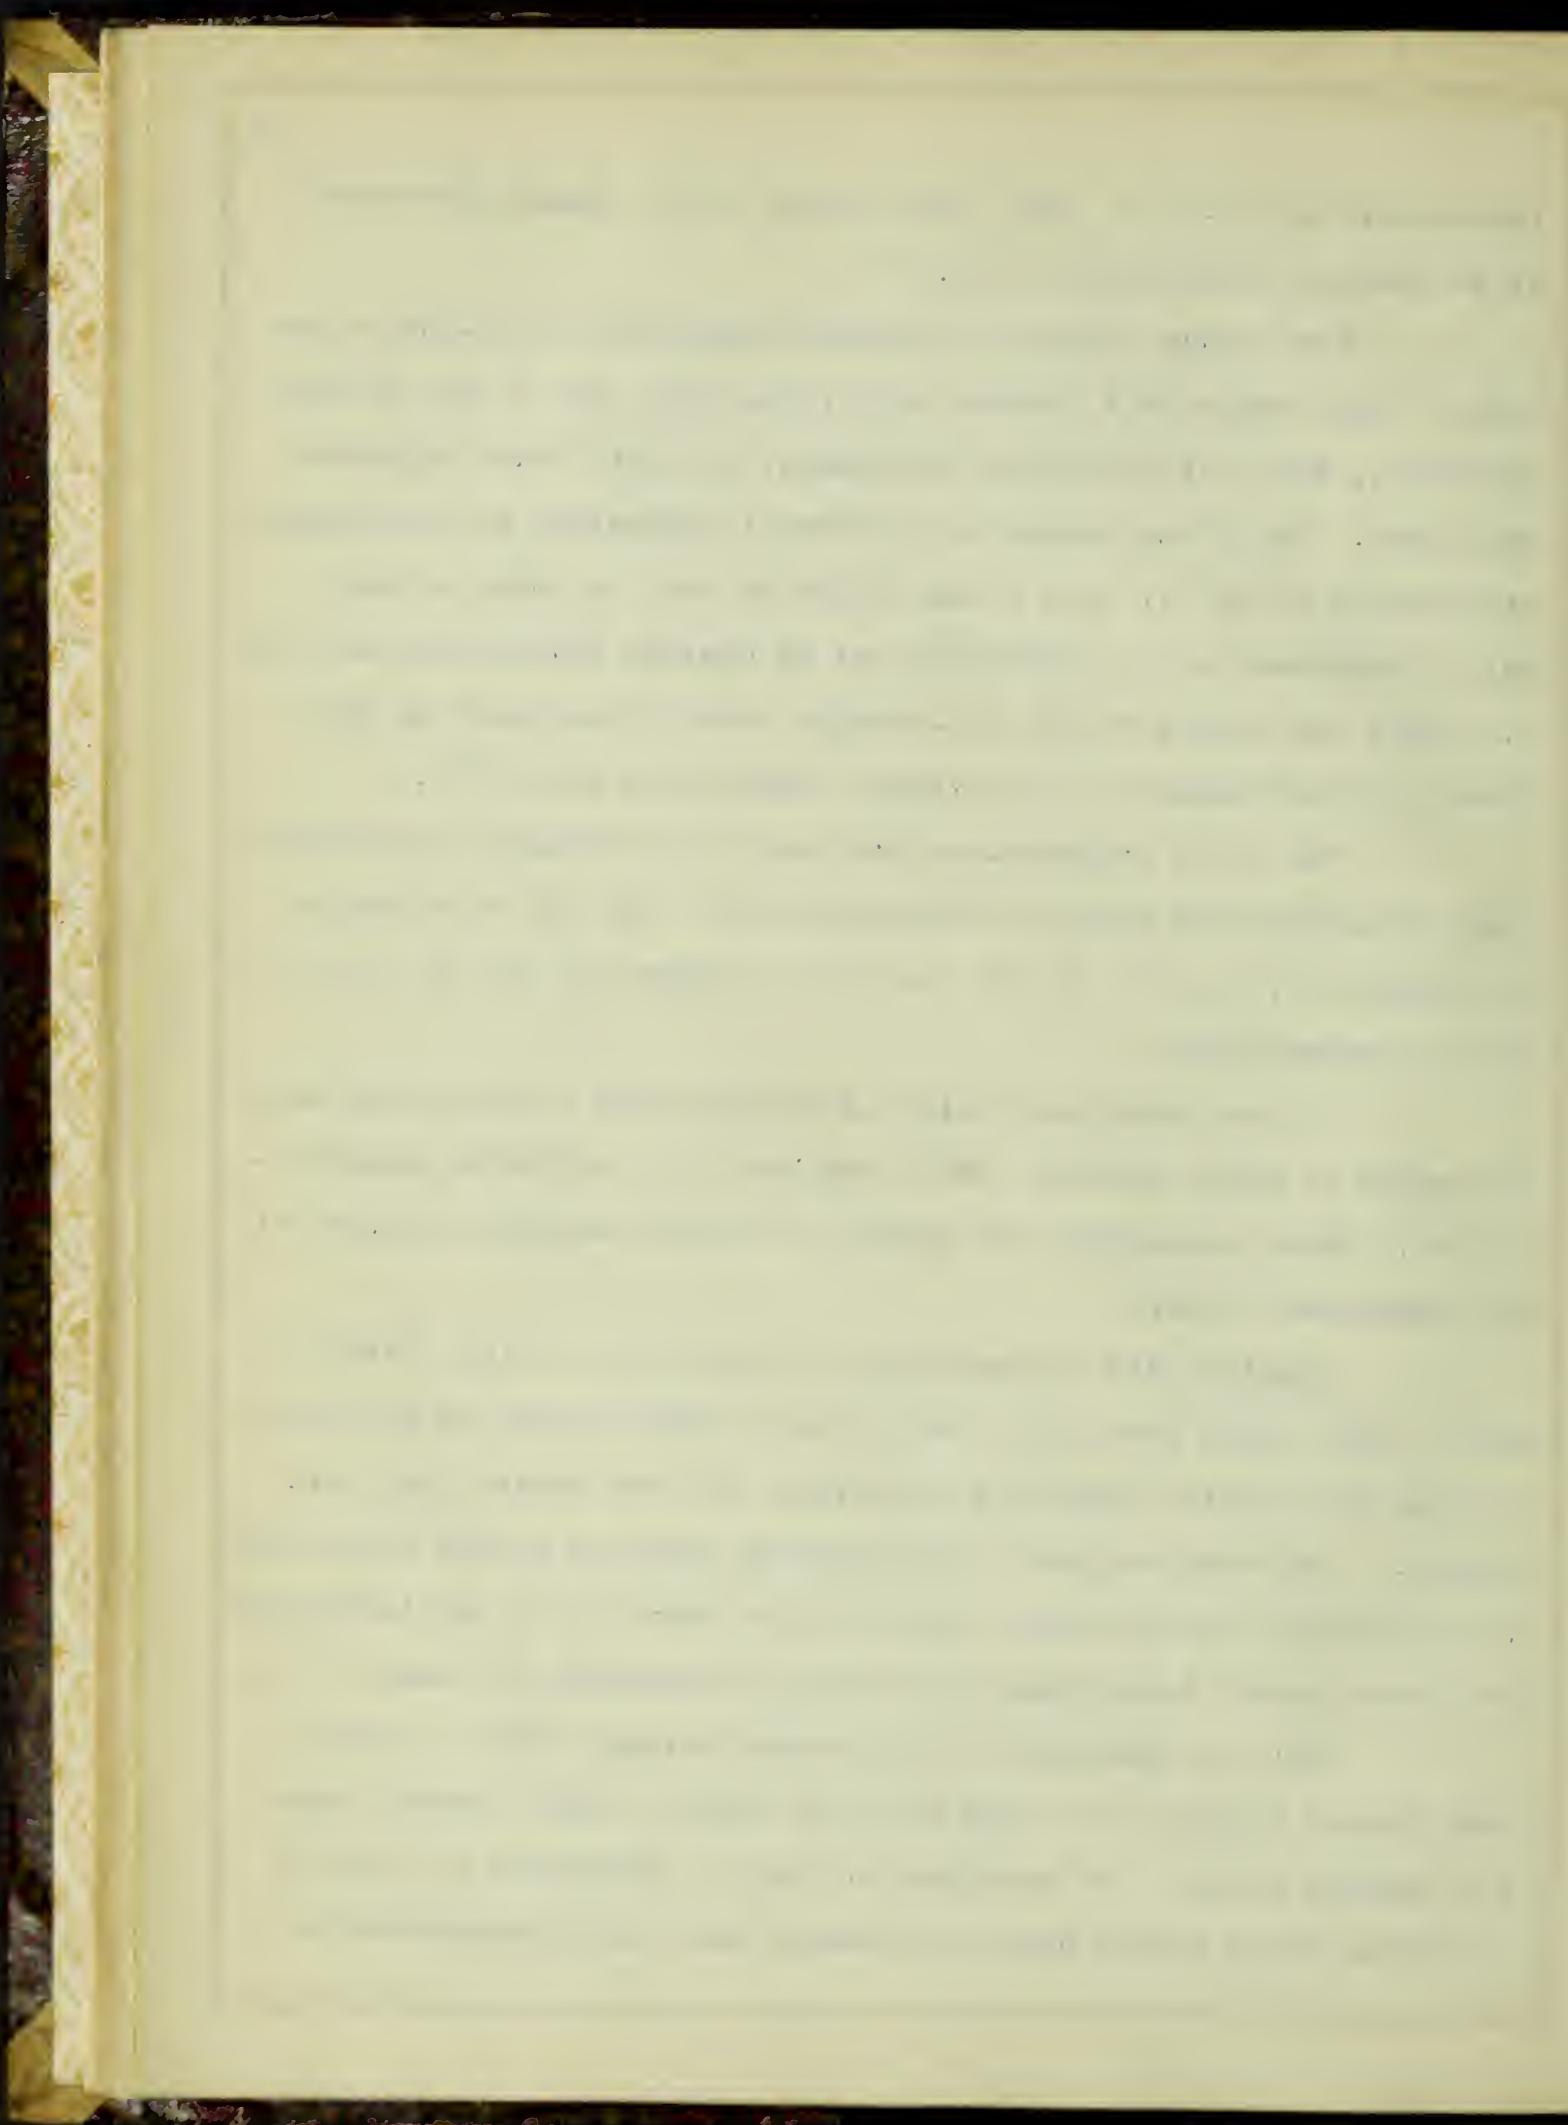

The second series of specimens comprised fifty-one 6-inch cubes. This series was divided into three sets, Set D with fifteen specimens, Set E with eighteen specimens, and Set F with eighteen specimens. Set D was stored in the Cement Laboratory at an average temperature of 68° F. Set E was stored in the ice chest of the Dairy Department of the University at an average temperature of 35.5° F. Set F was stored in the ice-storage room of the plant of the Twin City Ice Company, at an average temperature of 27.1° F.

The above temperatures represent the averages of the readings of maximum and minimum thermometers for each day of storage. See Tables 19, 21, 23, 27, 30, and 32, on pages 33, 34, 35, 39, 42 and 44 respectively.

All the specimens while in storage were covered with several layers of moist sacking, which was kept in a uniformly damp condition. Every precaution was taken to keep the moisture content of the specimens uniform.

Testing. All the specimens of the first series, Sets A, B and C, were taken from their respective storage places to the Theoretical and Applied Mechanics Laboratory one day before they were tested. They were weighed, their bearing surfaces coated with plaster of paris, and then were stored in the open air of the laboratory for about twenty hours under an average temperature of about 75° F.

All the specimens of the second series, Sets D, E and F, were tested in about one hour from the time of their removal from the storage rooms. Two specimens of Set F, designated F 17 and F 18, after being stored under an average mean daily temperature of

27.1° F. for forty-four days, were stored in the testing laboratory under an average daily temperature of about 70° F. for seven and twenty-one days, respectively, in order to gain sufficient strength to permit testing.

All the specimens were tested in compression in a Riehle testing machine of 100,000 pounds capacity. The load was applied in each test through a ball and bearing socket head at a speed of 0.10 inch per minute.

In the first series, five specimens each of Sets A, B and C were tested at an age of seven days, five specimens of each set at an age of fourteen days and five specimens of each set at an age of twenty-eight days. The results of these tests are given in Tables 24, 25 and 26 on pages 36, 37 and 38 respectively.

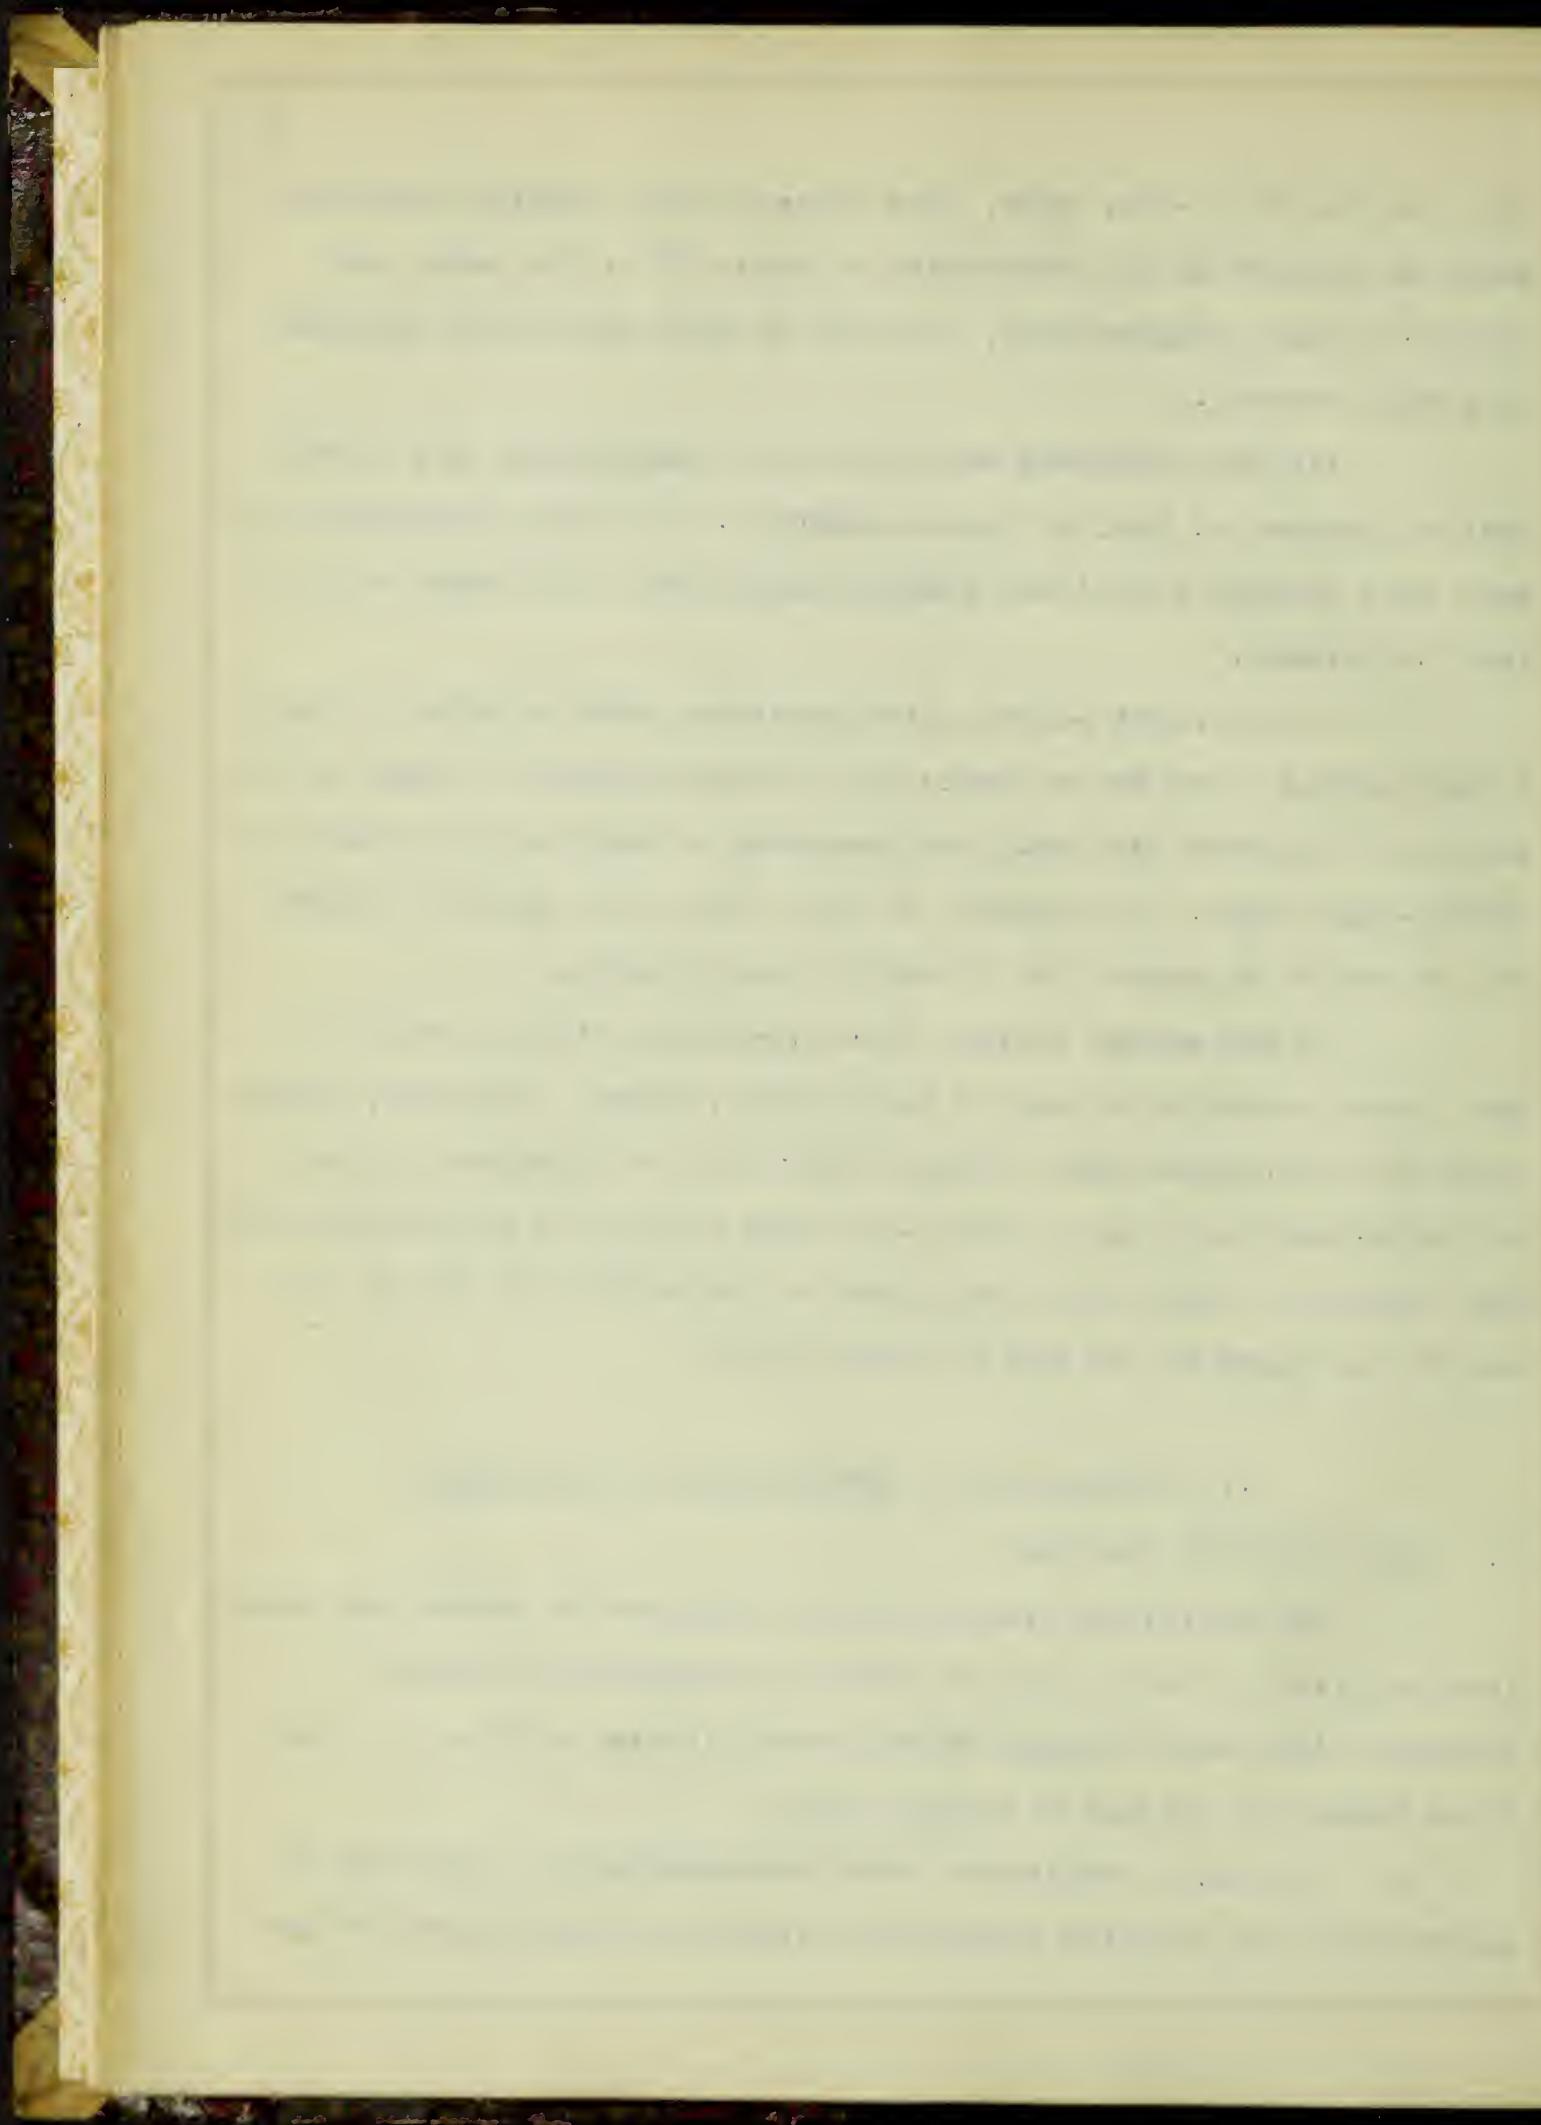

In the second series, three specimens each of Sets D, E and F were tested at an age of four, seven, eleven, fourteen, twenty-eight and forty-four days, respectively; and one specimen of Set F at forty-four days, one at fifty-one days and one at sixty-five days. The results of these tests are given in Tables 33, 34, 35, 36, 37, and 38, on pages 45, 46 and 47 respectively.

III. DISCUSSION OF EXPERIMENTS ON CYLINDERS.

5. EXPLANATION OF DIAGRAMS.

The individual unit ultimate strengths in pounds per square inch as given in Tables 24, 25, and 26, on pages 36, 37 and 38 together with their average values, were plotted in Fig. 4, 5, and 6, on pages 21, 22 and 23 respectively.

To find a continuous curve representing for each set of experiments the relation between the crushing strength and the age,

the average strength was first determined for each of the three ages; and then it was assumed that the curve sought would have the form $y = ax + bx^2 + cx^3$, in which y is the average strength in pounds per square inch for each age, x the age in days, and a , b , and c are constants to be determined. The average strength for each age gives a value for y , and the age for each group gives a value for x ; and therefore we have three equations with three unknown quantities. Solving these three equations for Set A, page 21, gives $a = +187.2$, $b = -9.74$ and $c = +0.174$. Substituting these values in the above equation gives the numerical equation stated on page 21, and represented by the — — line.

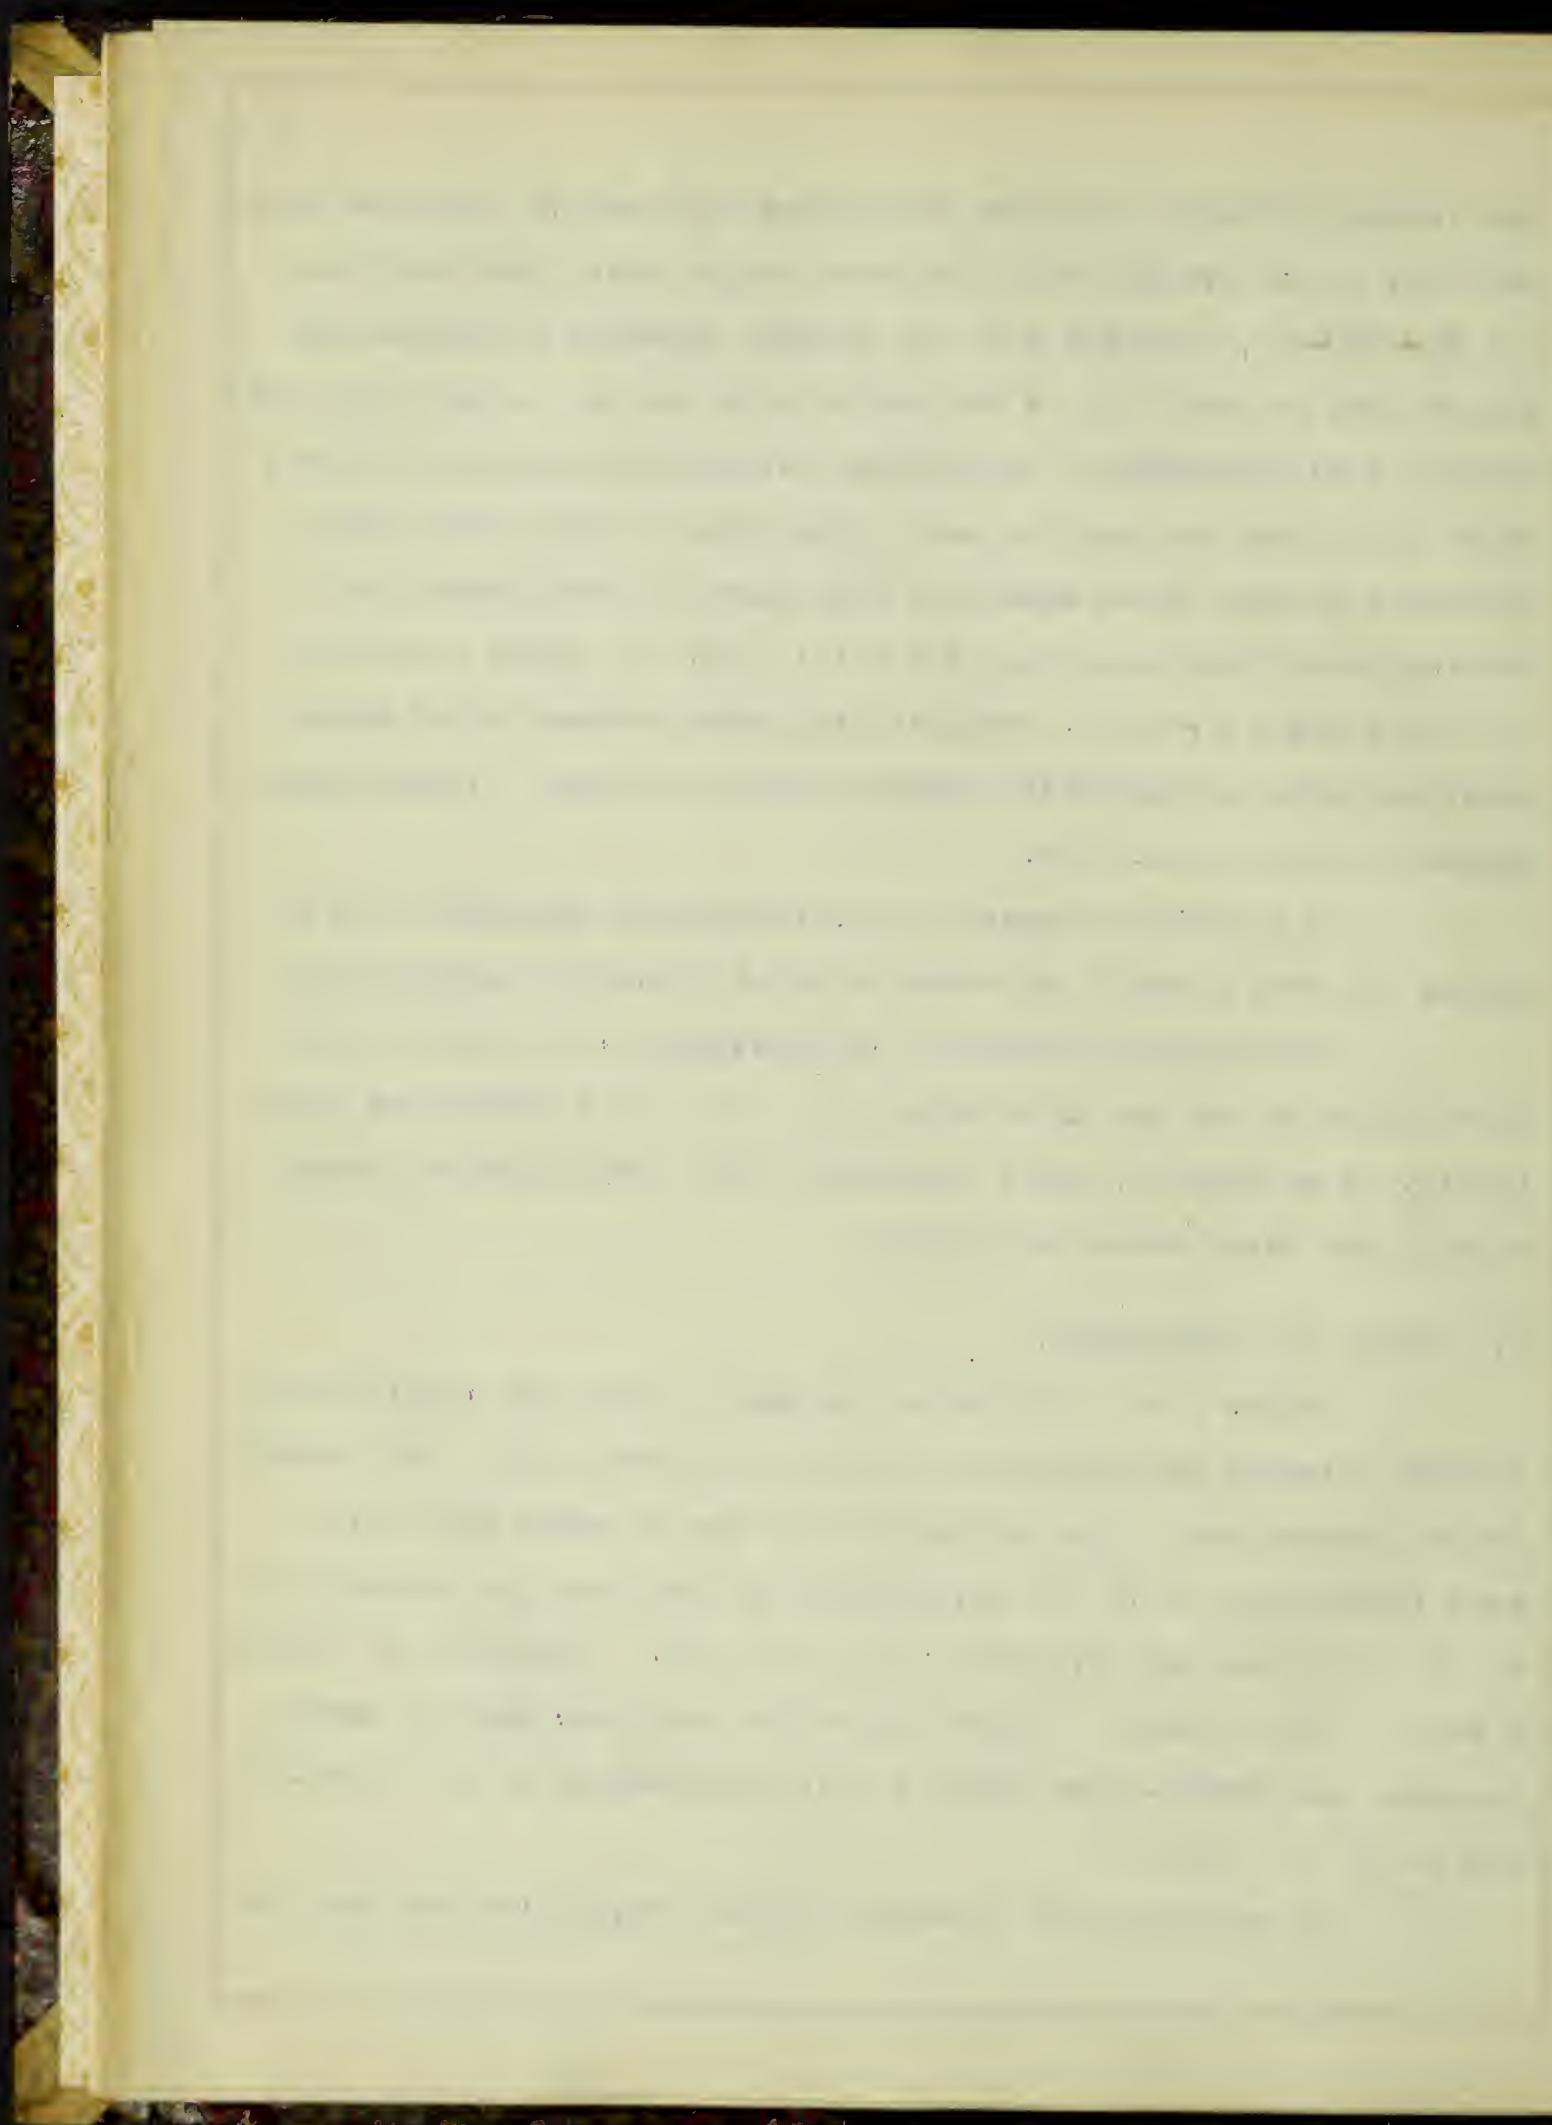

By a similar process the corresponding equations were obtained for Sets B and C, as shown on pages 22 and 23 respectively.

The numerical values of the constants a , b , and c in the above equation for the three sets A, B, and C, are plotted as shown in Fig. 10 on page 27, and a continuous curve was sketched through each of the three groups of points.

6. EFFECT OF TEMPERATURE.

Tables 1 to 3 inclusive, on page 11, show the relationship between strength and temperature at the different ages. For example, Table 1 shows that if the strength at an age of seven days for a mean temperature of 72° be represented by 100% then the strength at 48° is 91.7% and the strength at 30° is 74.4%. Similarly for Tables 2 and 3. The average of these tables for the three ages of seven, fourteen and twenty-eight days is that the strength at 48° is 92.5%, and at 30° is 71.6%.

To determine the relation between temperature and age, we

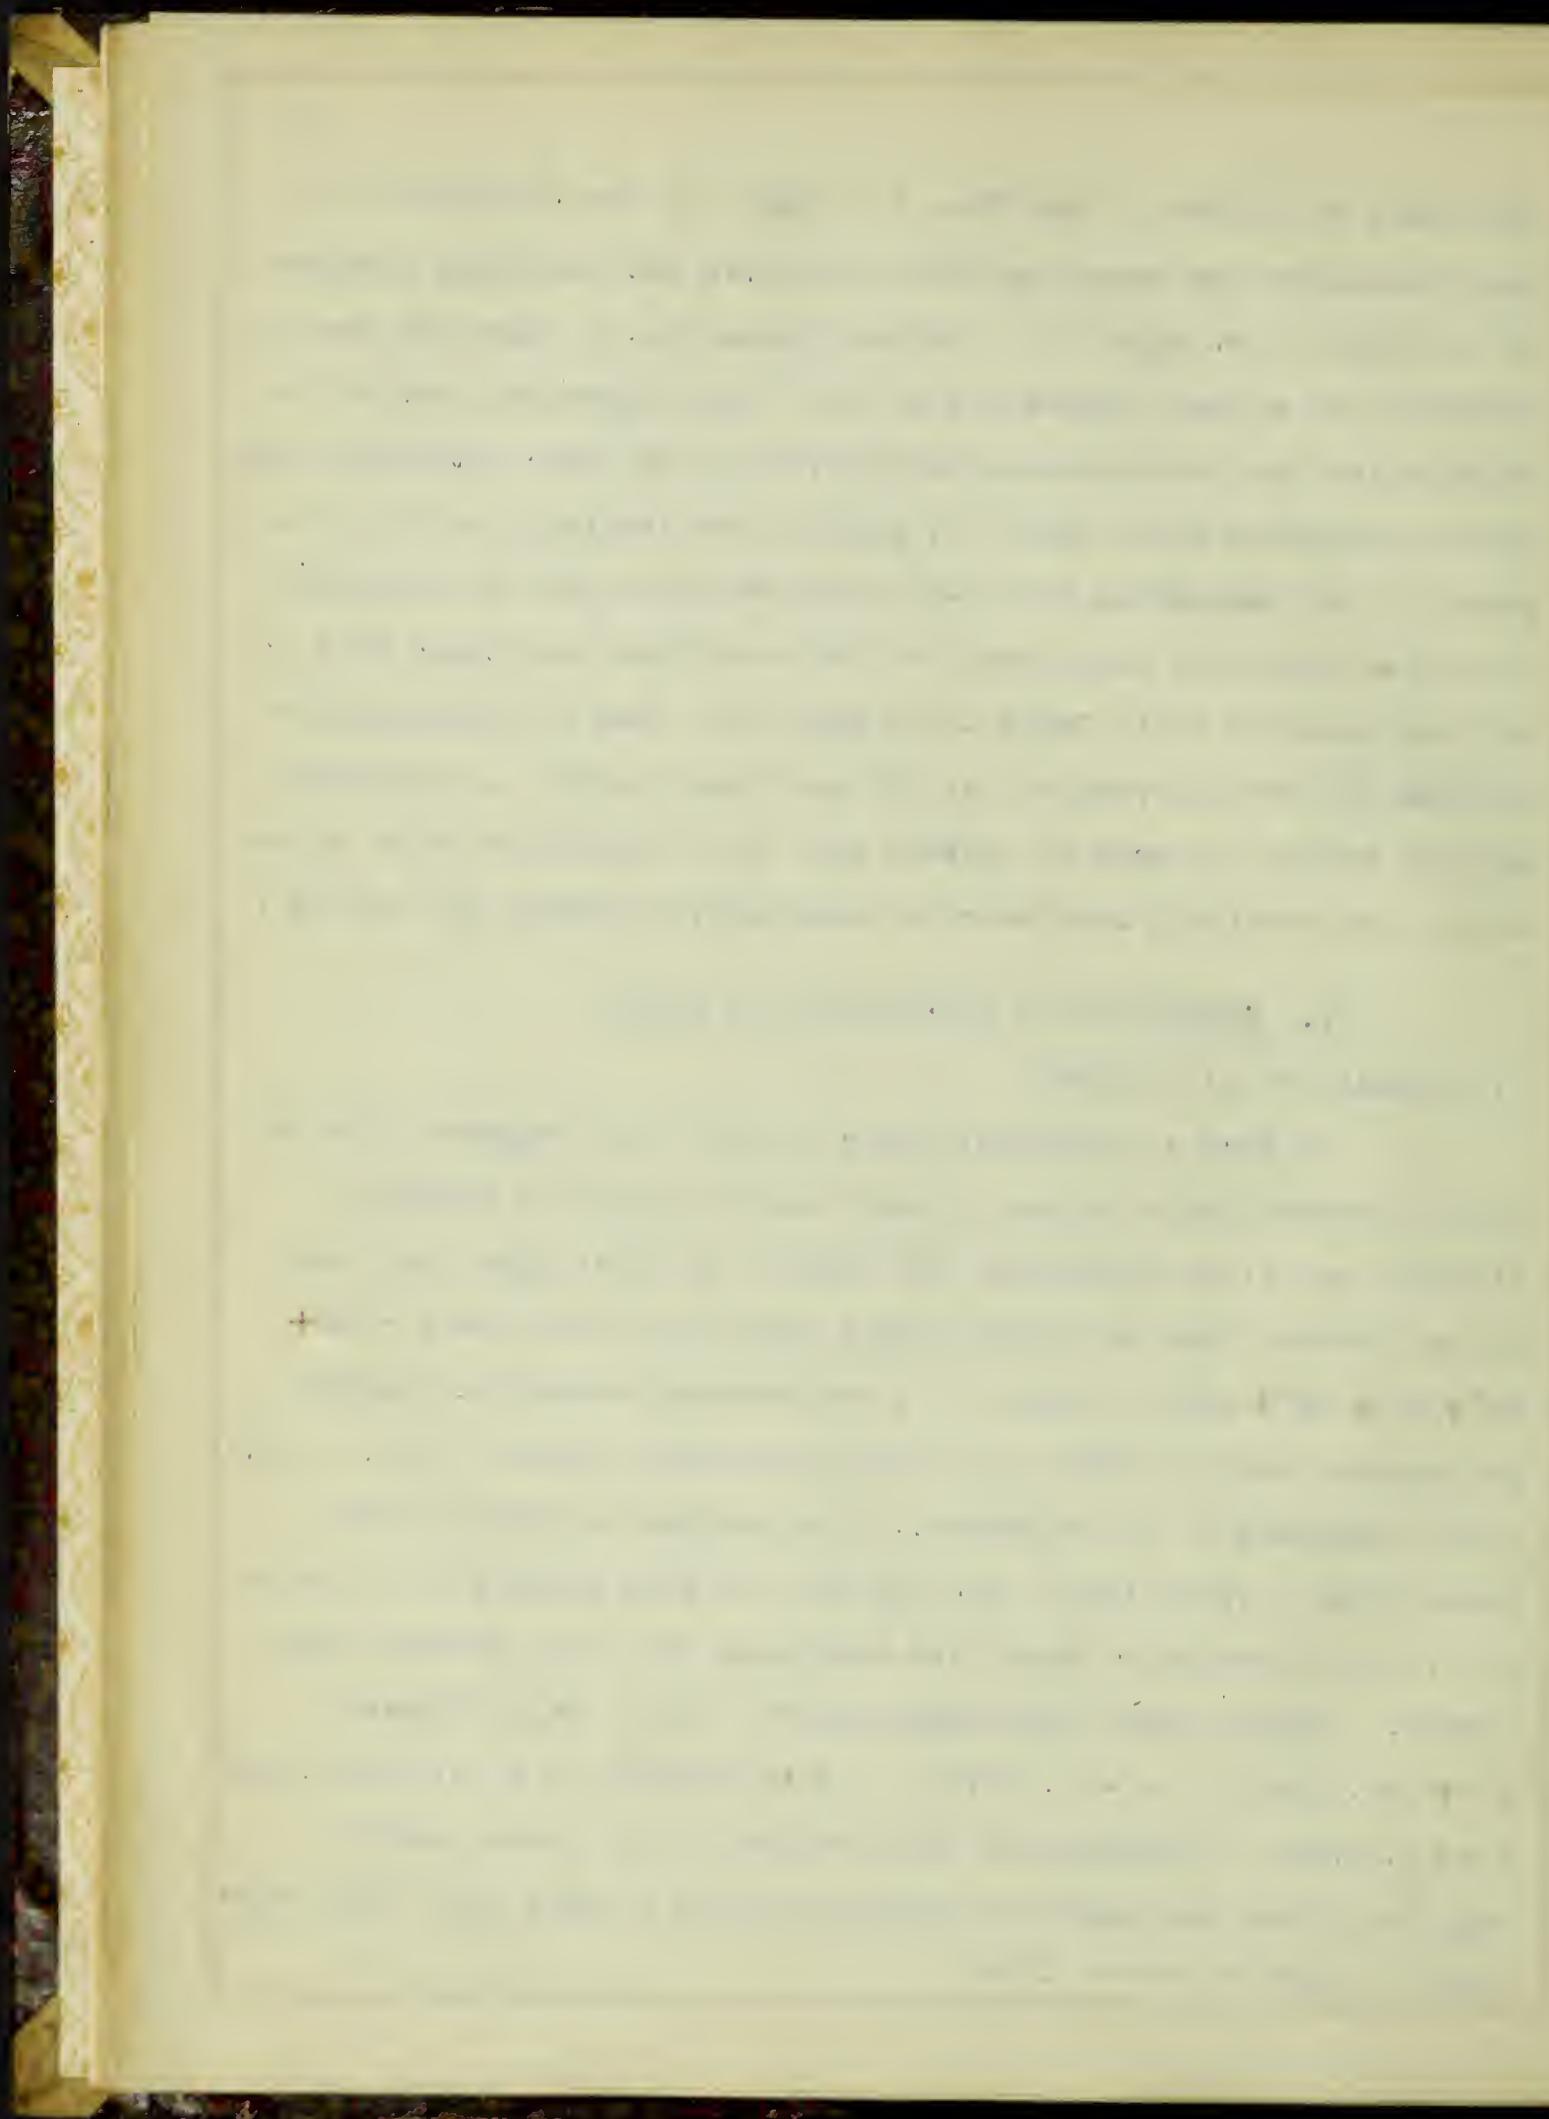

proceeded as follows: From Fig. 4 on page 21 the increments for each successive day were read from the curve and tabulated opposite 30° in Table 11 on page 15. Similarly from Fig. 5, page 22, the increments for a mean temperature of 48.5° was determined, and by interpolation the corresponding increments for 48° were determined and written opposite 48 in Table 11, page 15, and similarly in Fig. 6 on page 23, the increments for 72.8° were determined and by interpolation from these the increments for 72° were found and these were written opposite 72° in Table 11 on page 15. Then by interpolation between the several results for 30° and those for 48° , the intermediate values for each of several ages and temperatures were determined, and similarly results were interpolated between 48° and 72° .

IV. DISCUSSION OF EXPERIMENTS ON CUBES.

7. EXPLANATION OF DIAGRAMS.

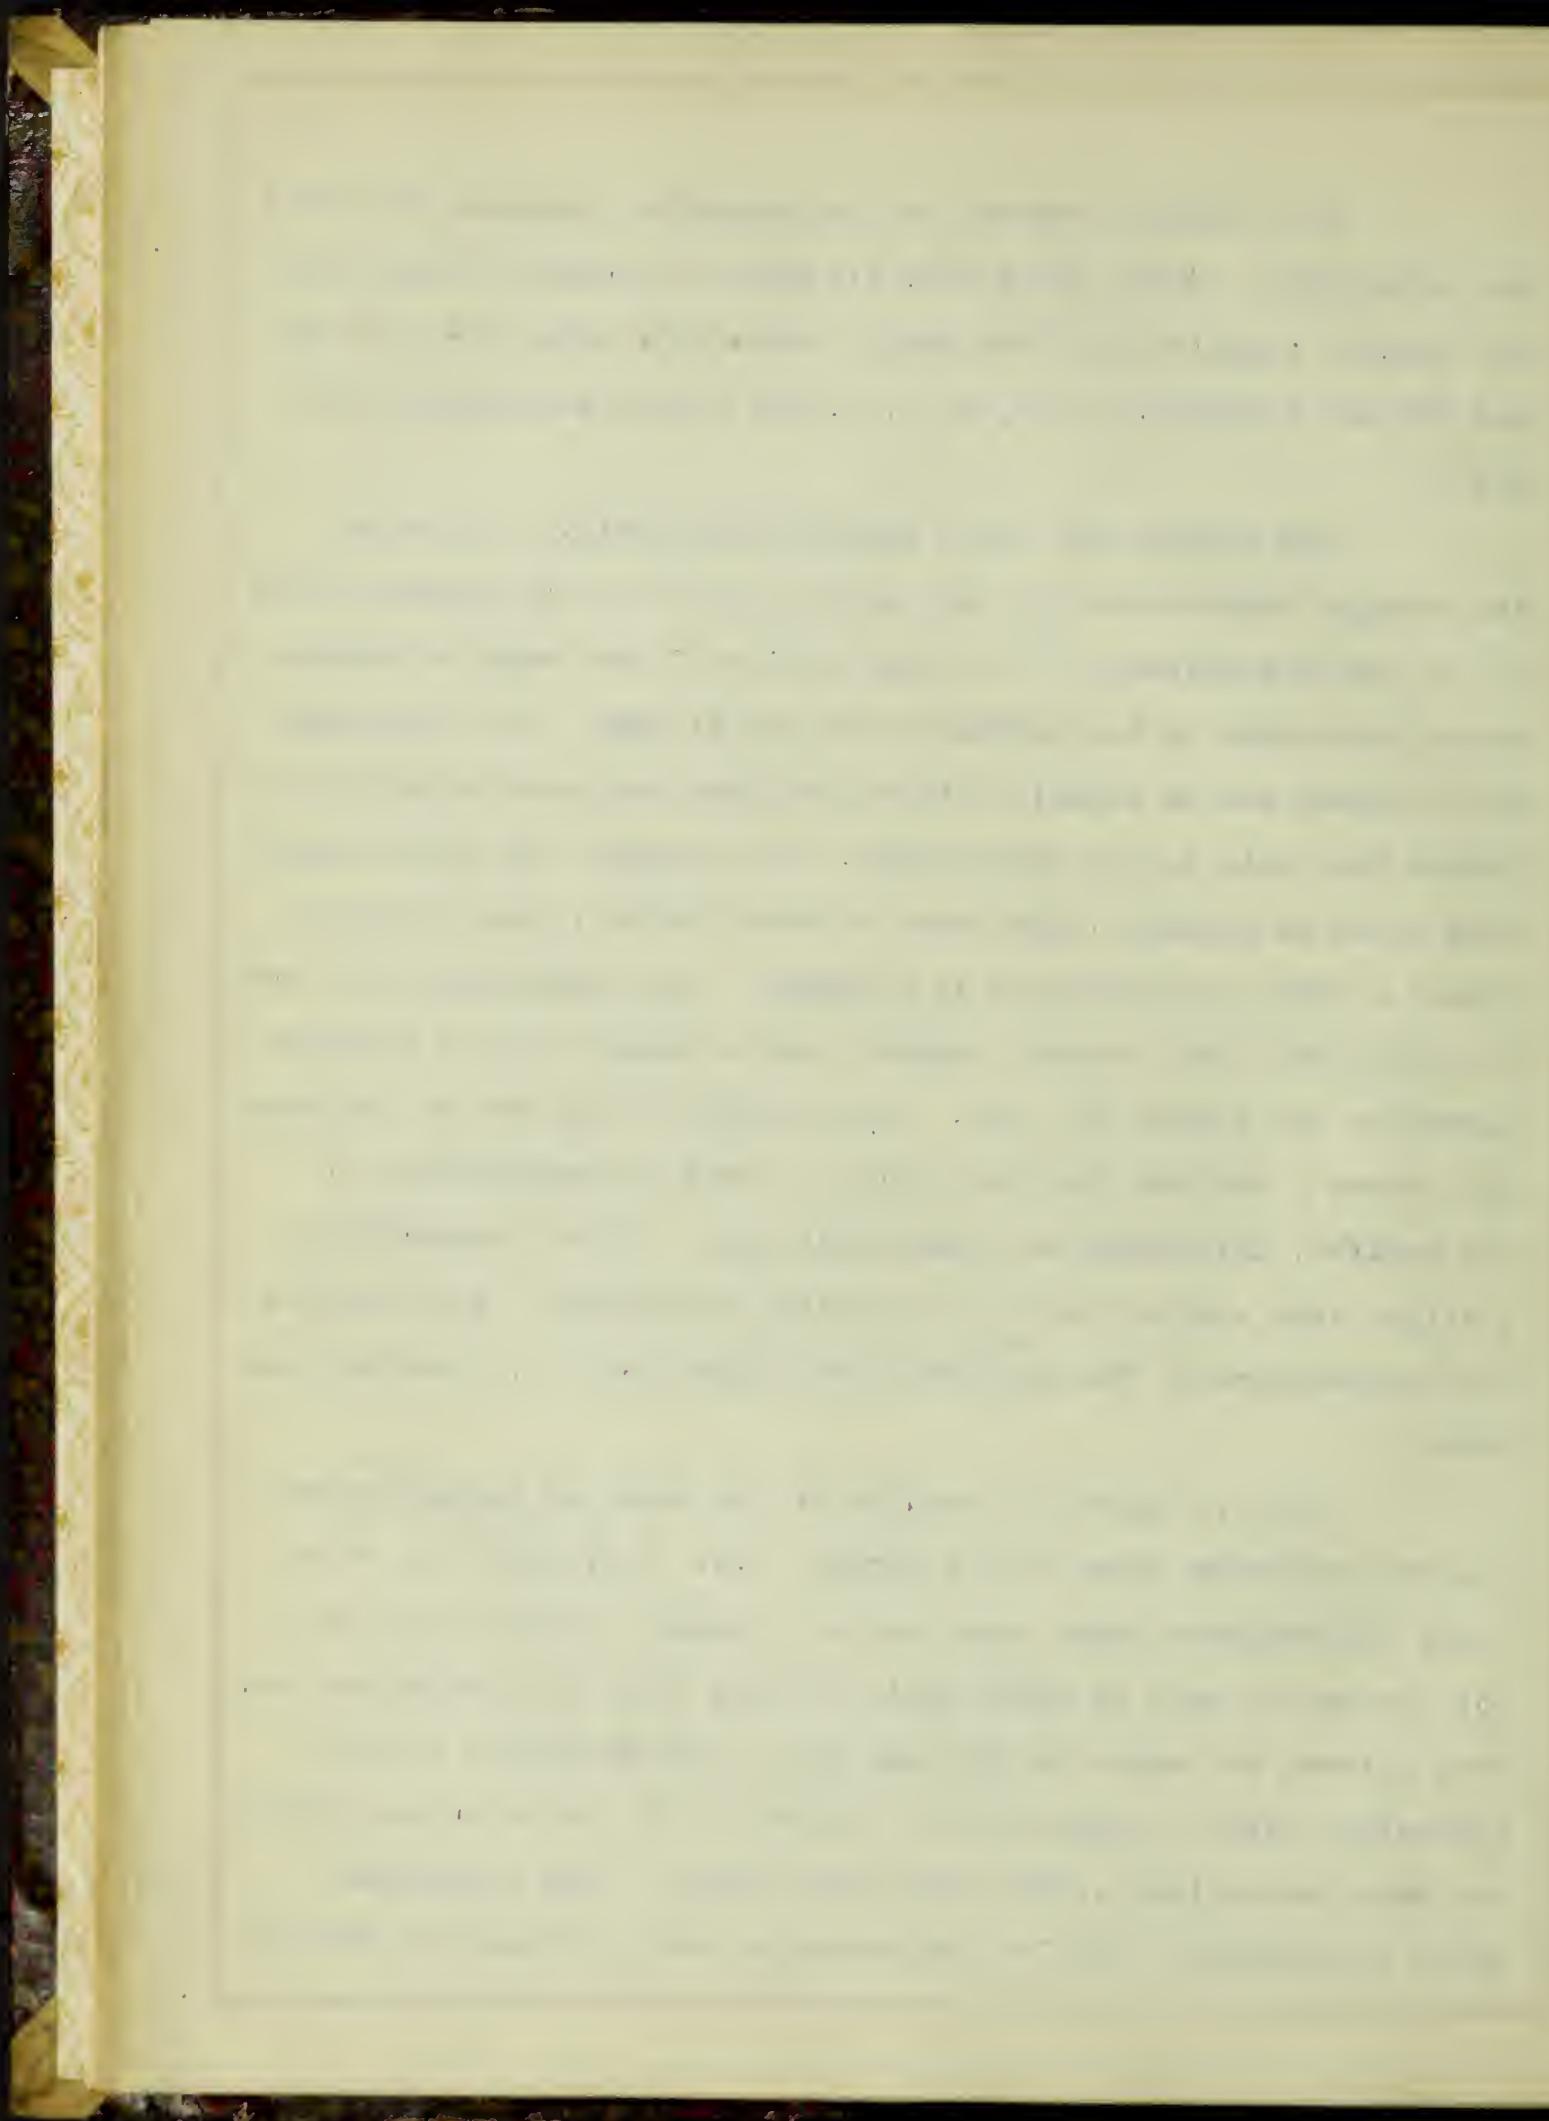

To find a continuous curve for Set D to represent the relation between the crushing strength and the age, the average strength was first determined for each of the five ages; and then it was assumed that the curve sought would have the form $y = ax + bx^2 + cx^3 + dx^4 + ex^5$, in which y is the average strength in pounds per square inch for each age, x the age in days, and a , b , c , d , and e are constants to be determined. The average strength of each group gives a value for y , and the age for each group gives a value of x ; and therefore we have five equations with five unknown quantities. Solving these five equations for Set D, page 24 gives $a = +384.91608$, $b = -73.193729$, $c = +7.685873$, $d = -0.355945$, and $e = +0.005724$. Substituting these values in the above general equation gives the numerical equation stated on page 24, and represented by the ——— line.

By a similar process the corresponding equation for Set E was determined. Since there were six ages of testing in this set, the general equation took the form $y = ax + bx^2 + cx^3 + dx^4 + ex^5 + fx^6$ and the six constants, a, b, c, d, e, and f were determined as for Set D.

The results for Set F are plotted in Fig. 9, page 26. The average temperature for this set is 27.1° F., the minimum being 18° F. and the maximum 42° F. The details of the range of temperatures are shown by the curves at the top of page 26. The range was so great and so erratic that no satisfactory results can be obtained from this set of experiments. For example, the first seven days under an average temperature of about 29° deg., the concrete showed a nearly uniform gain in strength. The temperatures for the next four days fell several degrees, and a slight drop in strength showed in the eleven day test. The strength at the end of fourteen days shows a decided increase owing to the high temperatures of the twelfth, thirteenth and fourteenth days. In all probability a slight thaw started during these high temperatures, and when the low temperatures of the succeeding days again set in, freezing took place.

Fig. 9, shows the results of the tests of sixteen cubes. The two remaining cubes of the series, i.e., F 17 and F 18, were badly disintegrated when taken out of storage, and were also so soft as not to make it worth while to test them; and therefore they were allowed to remain in the open air in the Materials Testing Laboratory under a temperature of about 70 F. for seven and twenty-one days respectively, when they were tested. This experiment shows conclusively that low temperatures merely retard the setting

action of concrete, and that alternating high and low temperatures cause disintegration and crumbling.

No attempt was made to derive a mathematical relation between the age and strength for Set F because of the inconsistency of the results.

8. EFFECT OF TEMPERATURE.

Tables 4 to 10 inclusive on pages 12, 13 and 14 show relative strength for different temperatures at different ages. For example, Table 4, page 12 shows that if the strength at 68° be considered 100%, then the strength at 35.5° is 57.3% and that at 27° is 49.6%, and similarly for Tables 5, 6, 7 and 8. Tables 9 and 10 show the percentage of strength of the different results in comparison with the strength at seven and twenty-eight days respectively.

Table 12, pages 16 and 17, gives the daily increment in strength due to a variation in temperature and age. This table was deduced in a manner exactly similar to that described for Table 11 on page 15, except that in the case of Table 12 the interpolation is between 35° and 68° .

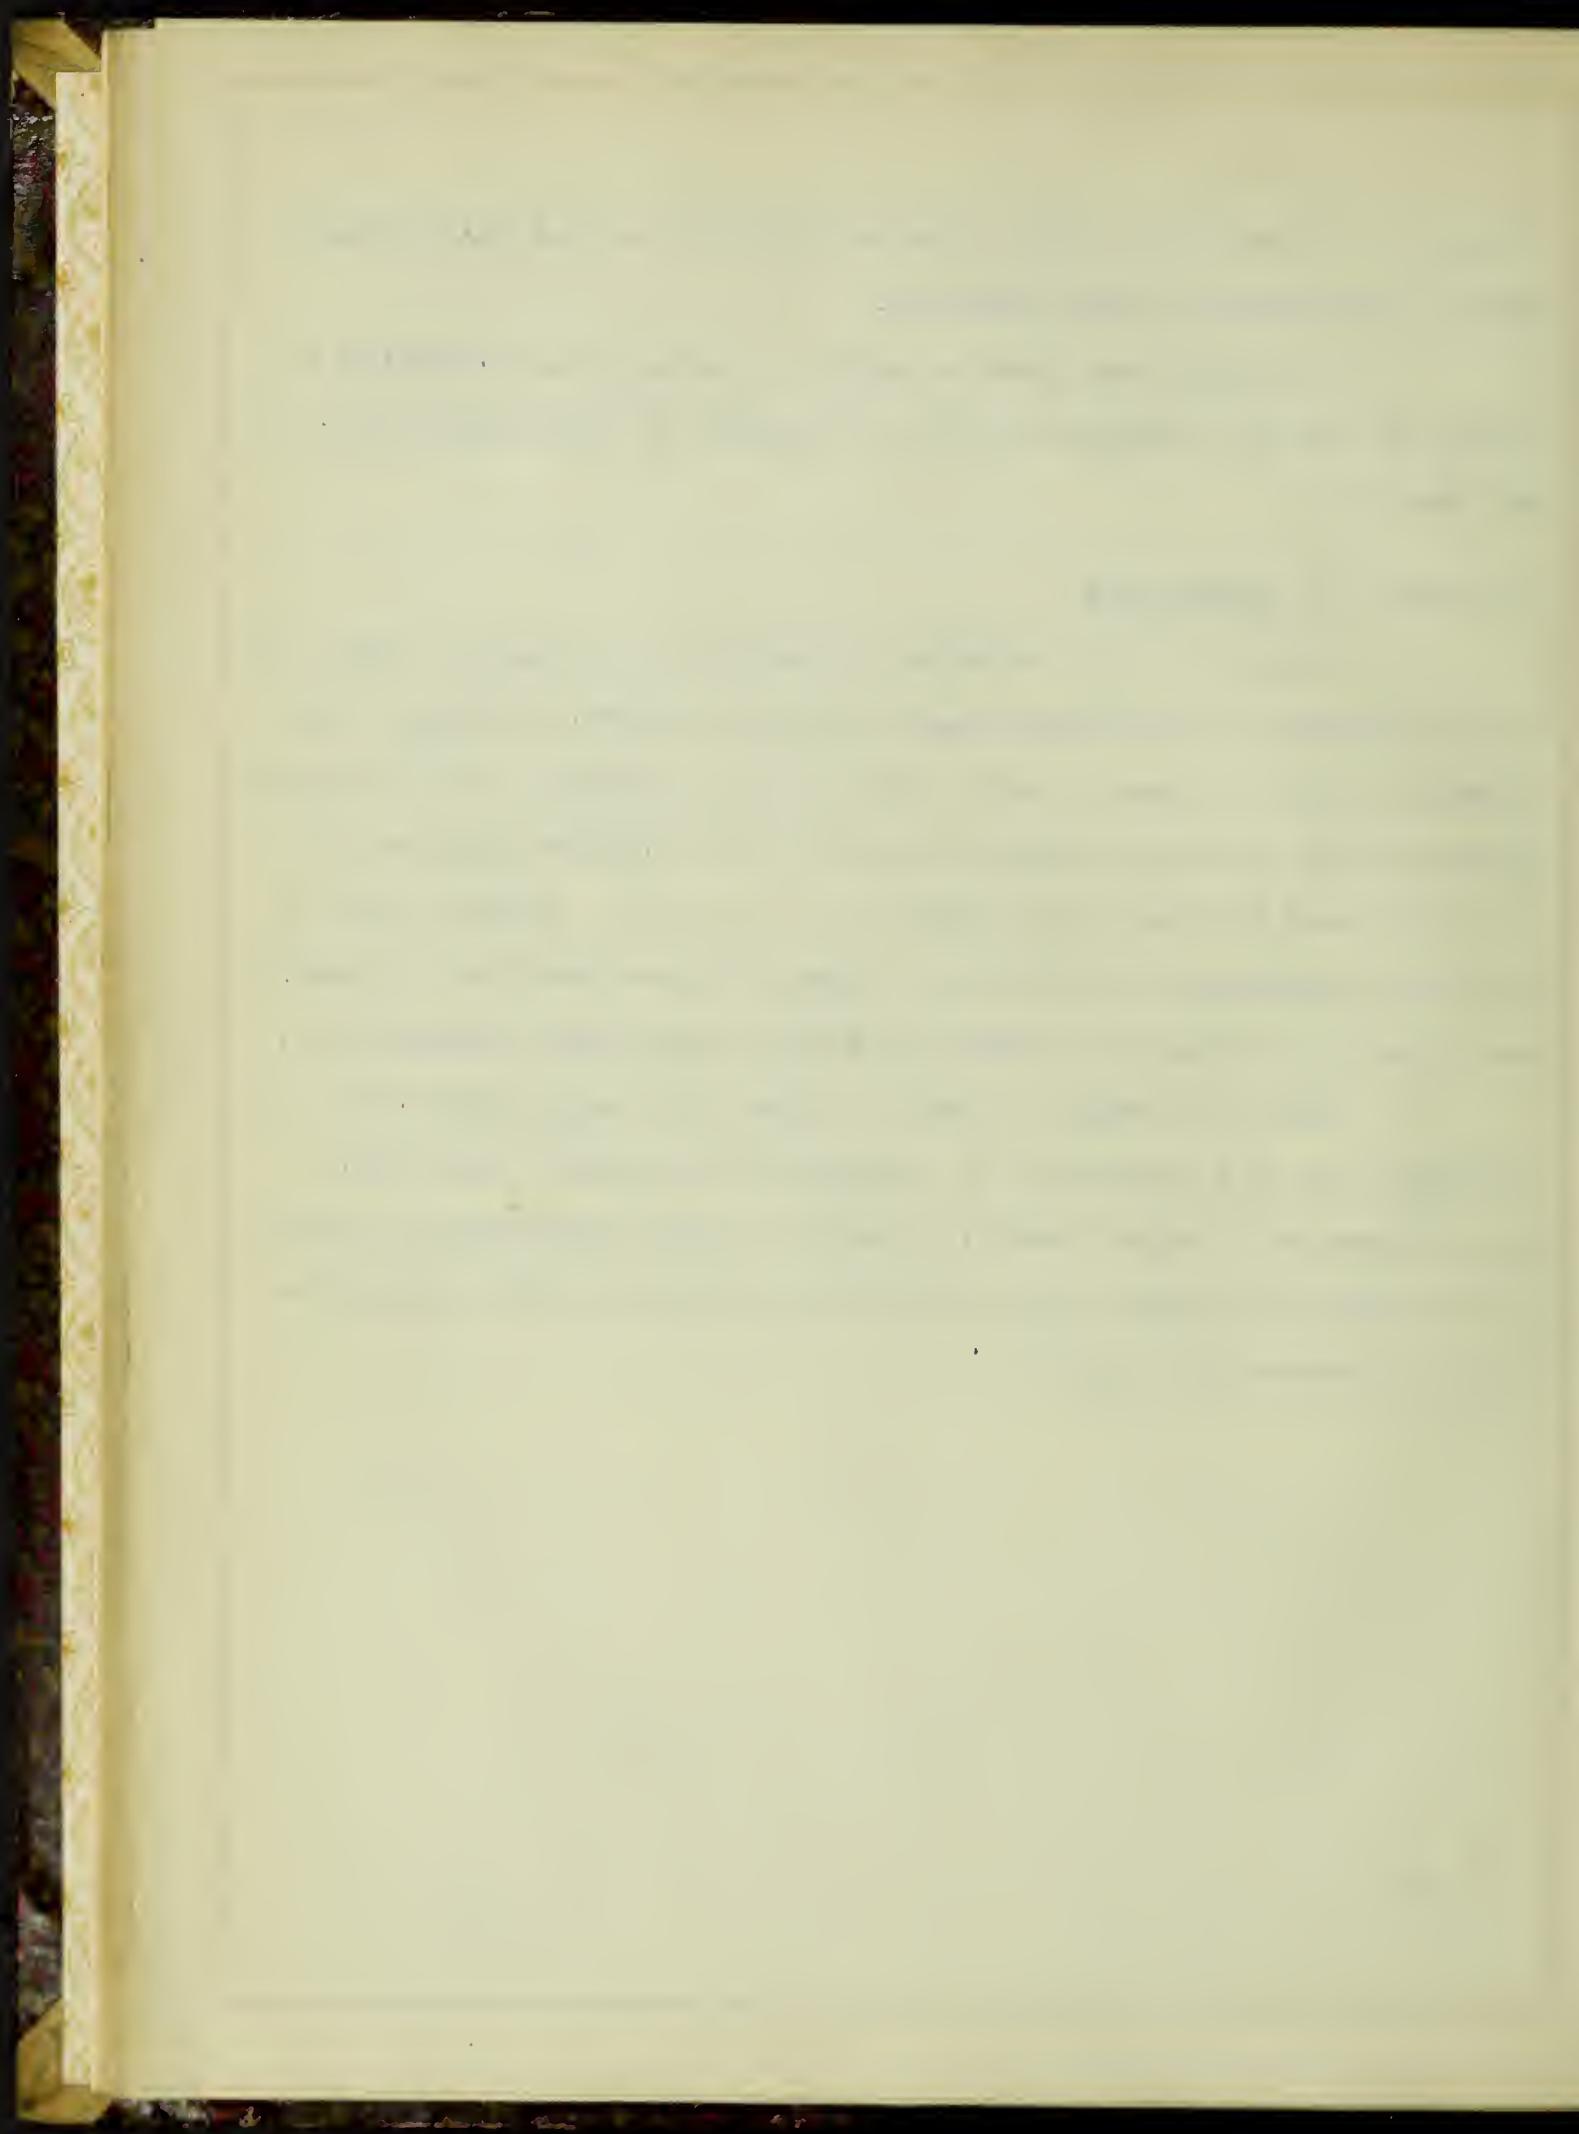

Table No. 1.

COMMUNALISM

Communalism
is a political movement
which aims at creating
a separate state for
the Hindus.

Majority Hindus
are against it.

V. DETAILS OF OBSERVED DATA.

9. TESTS OF MATERIALS.

29

CEMENT TESTS.

Plasticity: by Penetration Method.

Table No. 13.

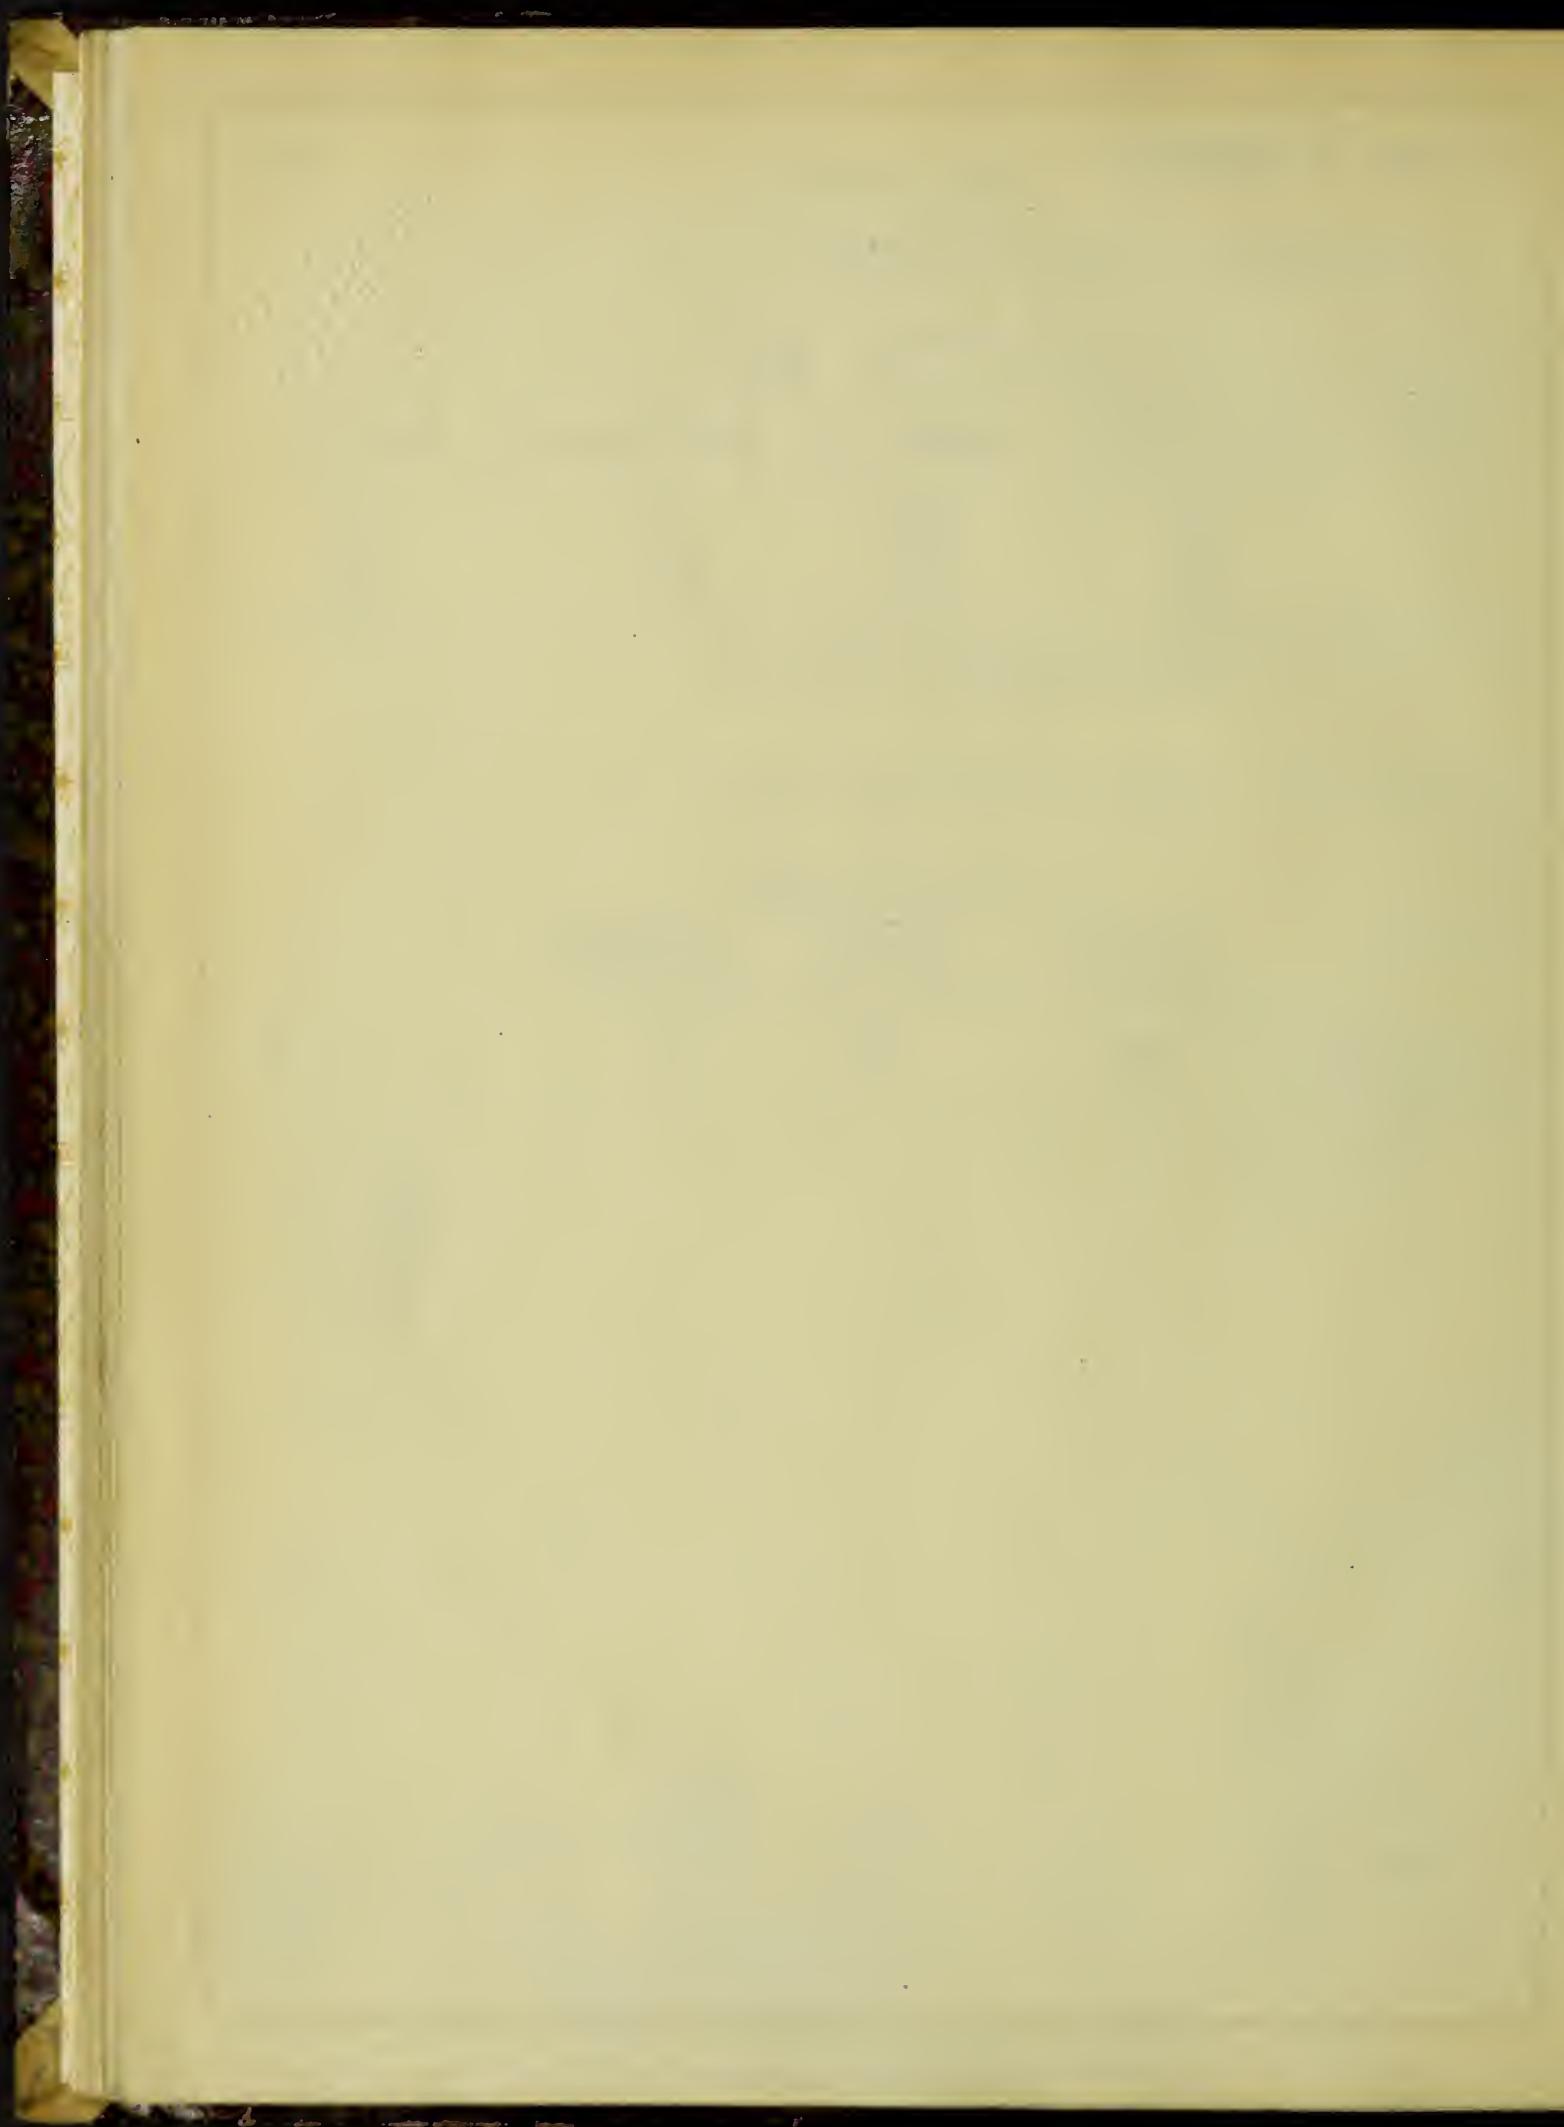

Trial No.	Gms. Cement	Percent H ₂ O	Penetration mm.	Time sec.
1	500	23.0	0.2	30
2	500	23.5	17.2	30
3	500	23.0	12.0	30
4	500	22.5	7.0	30

23% water gave best results.

Fineness: Sample of 1000 units used.

Table No. 14.

No. of Sieve	Units Retained	retained on sieve.
200	160	16
100	29	2.9

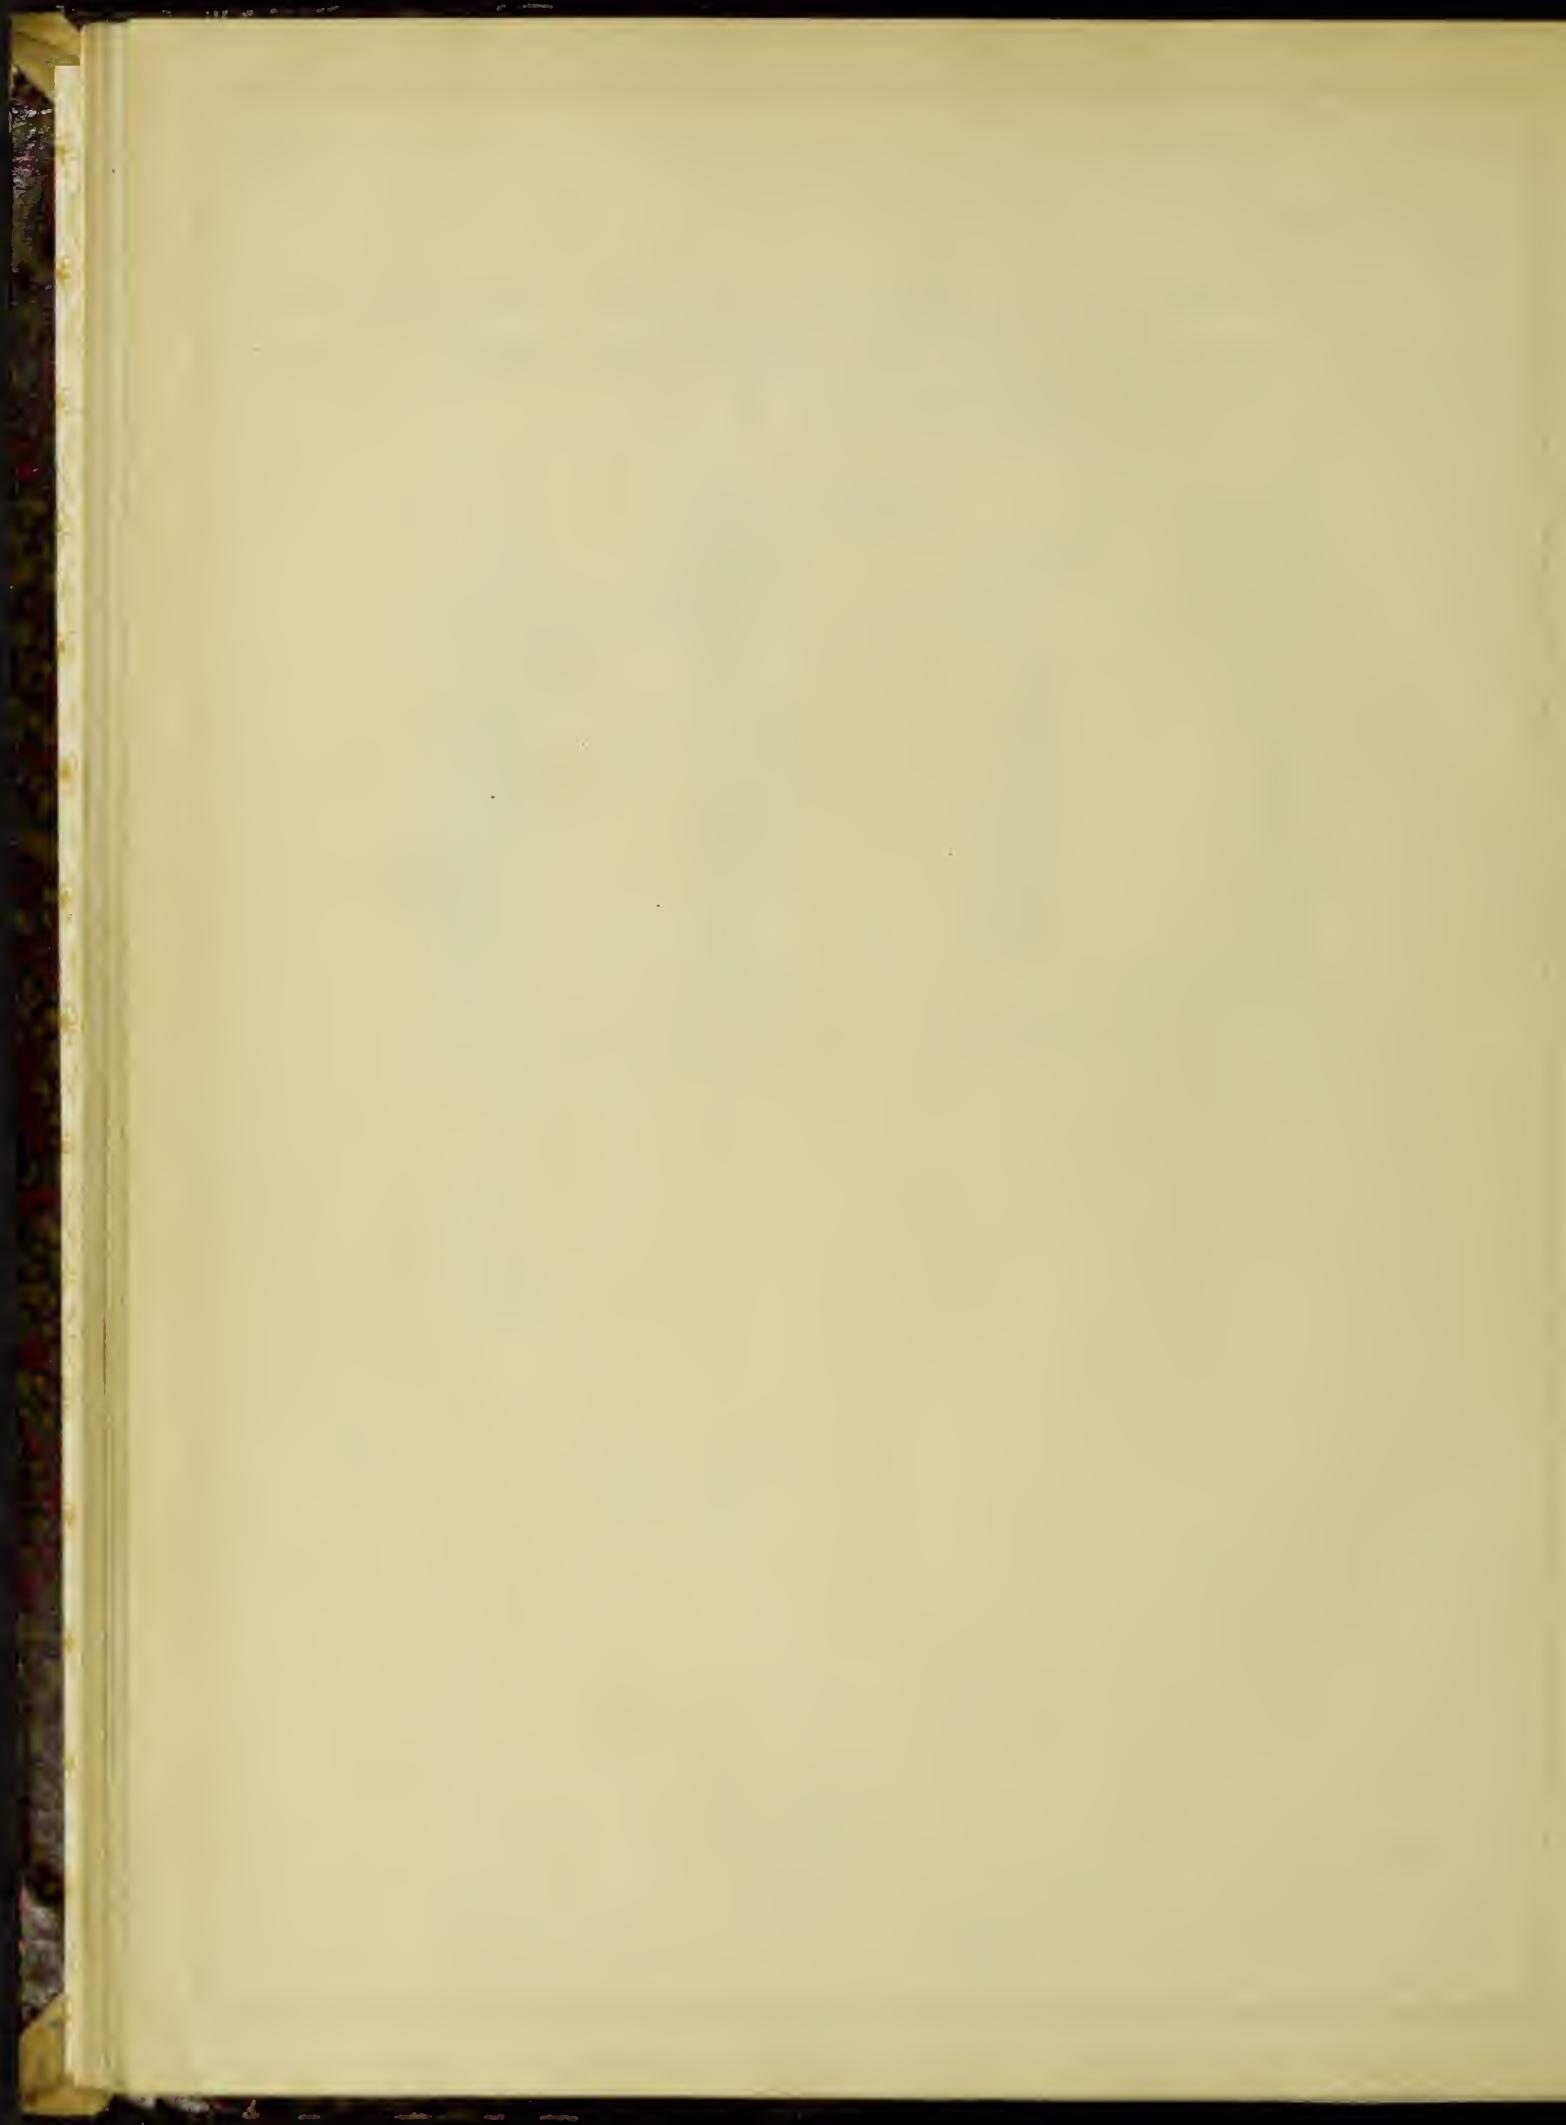

TEST OF SAND:-

The sand used was placed in a dryer for thirty-six hours and then a sample of 1000 grams was placed upon a nest of standard sieves and sifted for forty minutes.

Results.

Table No. 15.

No. of Sieve	Size of Mesh	Grams Retained	% Passing
$\frac{1}{4}$.20	4.4	99.99
5	.10	113.7	99.55
10	.073	150.1	88.13
20	.034	215.8	73.17
40	.015	212.2	51.59
60	.009	221.2	30.34
74	.0078	27.4	5.22
100	.0045	20.8	4.48
150	.0033	10.5	2.30
200	.0027	3.9	1.75
Passing 100		13.0	1.30
Total =		999.9	

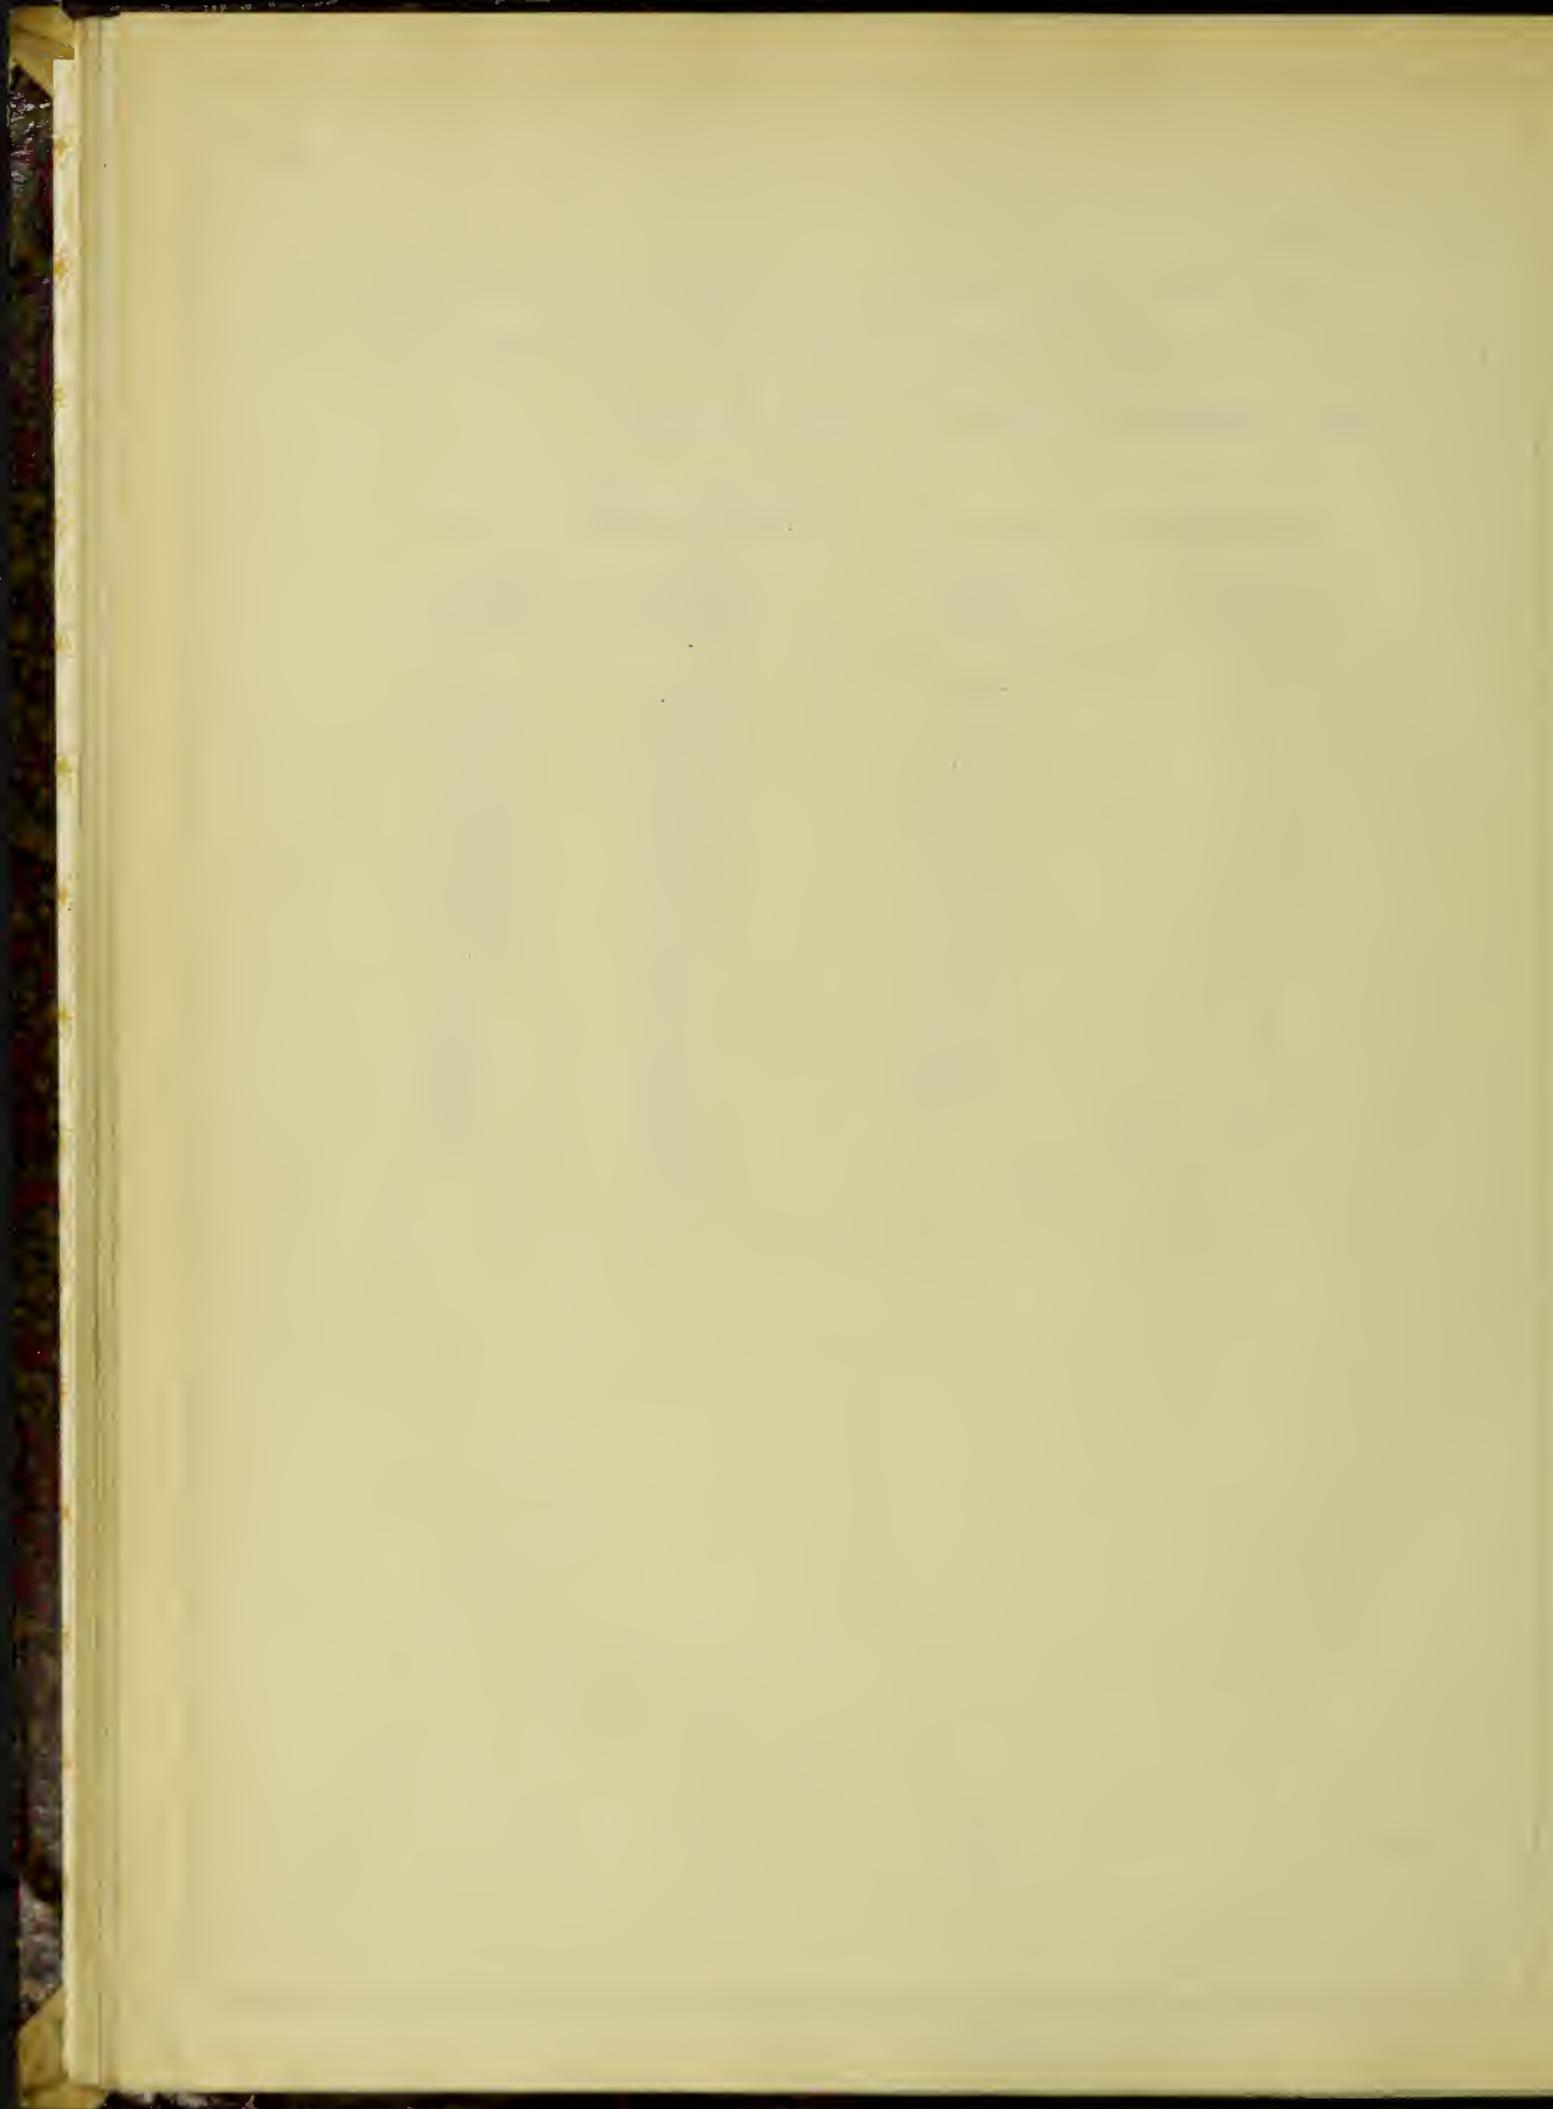

TEST OF STONE:-

The stone, like the sand, was placed upon the dryer for thirty-six hours and a sample of 2500 grams was placed upon a nest of standard sieves and sifted for forty minutes.

Results.

Table No. 16.

No. of Sieve	Size of Mesh	Grams Retained	% Passing
1/2	0.5	323.0	99.99
1/4	0.20	1008.0	86.8
5	0.16	615.0	46.5
8	0.0955	100.6	22.1
10	0.073	58.0	18.5
16	0.042	105.4	15.75
20	0.034	15.0	11.5
30	0.022	21.1	10.95
40	0.015	10.5	10.1
60	0.009	67.0	9.7
74	0.0078	12.1	7.0
100	0.0045	19.8	6.52
150	0.0033	22.3	4.73
200	0.0027	8.5	4.82
Passing 200		112.1	4.48
	Total =	998.4	

COMBINATION OF STONE AND SAND CURVES:-

The stone and sand curves were combined in order that the curve for aggregate might be compared with the ideal curve, a parabola. In combining the curves, 3500 grams (the combined weight of stone and sand) was used as 100% and the amounts of sand and stone passing the same sieve were added and the percentage passing calculated.

Table No. 17.

No. of Sieve	Size of Mesh	Amount of sand retained	Amount of stone ret'd	Total	% passing
$\frac{1}{2}$.50		323.0	323	99.99
$\frac{1}{4}$.20	4.4	1008.0	1012.4	91.2
5	.16	113.7	615.0	748.7	62.4
8	.0955		100.6	100.6	41.0
10	.073	150.1	58.0	208.1	38.1
16	.042		105.4	105.4	32.1
20	.034	215.8	15.0	230.8	29.1
30	.022		21.1	21.1	22.5
40	.015	212.5	10.5	222.5	21.9
60	.009	221.5	67.0	288.2	15.6
74	.0078	27.4	12.1	39.5	7.3
100	.0045	26.8	19.8	46.6	6.2
150	.0033	10.5	22.3	32.8	4.9
200	.0027	3.9	8.5	12.4	3.9
passing 200		13.6	112.1	125.7	3.6

From the combined curve it can be seen that there was an excess of large material. This is undoubtedly the cause of the visible voids which reduced the area and thereby weakened some of the specimens. No efforts were made to make the combined curve take the direction of the ideal as it was the authors' idea to make the investigation as practical as possible.
